iberman · labeling boundaries and discrimination peaks Must know · core review

- **Categorical perception** in **Liberman and colleagues' results** includes abrupt changes in phoneme labeling, although the stimuli themselves progress through evenly spaced acoustic changes. Early stimuli receive mainly /b/ responses, middle stimuli mainly /d/ responses, and late stimuli mainly /g/ responses, even though F2 onset changes in equal acoustic steps.
- Discrimination is better near the /b/–/d/ and /d/–/g/ boundaries than within the stretches receiving one label. The one-step, two-step, and three-step comparisons all relate sensitivity to the location of those boundaries. Chance performance is about **50% correct** in these discrimination tasks.
- Wider physical separation generally improves performance, but the category relationship also matters. Sounds assigned to different phonemes are easier to distinguish than similarly spaced sounds assigned to the same phoneme.
- Predictions based on the labeling responses capture the boundary-related peaks in discrimination. Listeners retain some acoustic sensitivity beyond the simplest categorical prediction, so identification and discrimination are closely related without being identical measures.

is feel like this has a lot of tounge twister hard to really read it out loud or am i wrong

You're not wrong! Your explanation is scientifically accurate, but **some sentences are unnecessarily complicated and difficult to read aloud.** It feels like a tongue twister because several technical terms are packed together, and some sentences repeat similar ideas.

For example, "The one-step, two-step, and three-step comparisons all relate sensitivity to the location of those boundaries" is technically fine, but it doesn't flow naturally.

I'd recommend keeping the scientific detail while using **shorter sentences, more natural transitions, and simpler wording**. This would make it easier to read, memorize, and explain during an exam.

Revised version — clearer and easier to read aloud

> **Liberman · Labeling Boundaries and Discrimination Peaks**
>
> **Must know · Core review**
>
> - **Categorical perception** occurs when listeners hear sounds as distinct phonemes, even

Why this version works better

The revised version preserves all the important scientific concepts, including F2 onset, categorical perception, phoneme boundaries, acoustic distance, and discrimination predictions.

The main improvements are:

1. **Shorter sentences:** You don't have to process several complicated ideas in one breath.
2. **Less repetitive wording:** Terms like “boundaries,” “comparisons,” and “sensitivity” appear only where necessary.
3. **More natural explanations:** Phrases like “telling sounds apart” are easier to say than repeatedly using “discrimination sensitivity.”
4. **Clearer connections:** Each bullet introduces one main concept before explaining the experimental findings.

My recommendation: Use this style for your LING 285 study notes. It maintains the academic rigor needed for an exam without sounding like you're reading directly from a research paper.

okay make a prompt to make it like that i love how you did the revised version make it a genralized prompt not only for this slide

Here's a **generalized prompt** you can use for any lecture slide, study guide, textbook section, or set of academic notes. It follows the same style as the revised version you liked.

> Rewrite the following academic material into clear, natural, and easy-to-read study notes while preserving all important scientific, technical, and conceptual details.
>
> I want the writing to sound like a knowledgeable professor explaining the material clearly, rather than a dense textbook or research paper. The notes should be academically rigorous but also smooth, conversational, and easy to read aloud without sounding like a tongue twister.
>
> **Writing style and clarity:**
>
> - Use shorter, well-structured sentences that flow naturally when spoken aloud.
> - Avoid unnecessarily complicated sentence structures, awkward phrasing, and excessive technical language when simpler wording communicates the same meaning.

- Keep essential scientific and technical terminology, but explain concepts using clear, accessible language.
- Avoid repeatedly using the same technical terms when natural alternatives would improve readability.
- Use straightforward transitions that make the relationships between ideas easy to follow.
- Maintain a professional, academic tone without sounding overly formal, robotic, or overly simplified.
- Make the explanations easy to understand, remember, and explain during an exam.

Content and scientific accuracy:

- Preserve all important information, including definitions, mechanisms, experimental findings, numerical results, comparisons, and conclusions.
- Do not remove meaningful details just to make the writing shorter.
- Do not introduce new information, assumptions, or interpretations that are unsupported by the original material.
- Clearly explain relationships between concepts, especially cause and effect, experimental conditions, and differences between findings.
- Keep important distinctions and qualifications that are necessary for scientific accuracy.
- When discussing research, explain what researchers investigated, what they found, and what the findings demonstrate, whenever these details are provided.

Organization and formatting:

- Organize the material into concise but informative bullet points.
- Begin each bullet with a **bolded key concept or main finding**, followed by a clear explanation.
- Focus each bullet on one central idea while including the supporting details needed to understand it.
- Use complete sentences rather than fragmented notes or overly abbreviated phrases.
- Keep paragraphs within bullets relatively short and easy to follow.
- Preserve the logical progression of the original material.
- Avoid unnecessary repetition between bullets.

Important writing preference:

Prioritize natural readability over complicated academic phrasing. I should be able to read each bullet aloud smoothly, understand it on the first reading, and explain it to someone else without having to mentally rephrase the sentence.

However, do not sacrifice scientific accuracy, important details, or conceptual depth for simplicity. The goal is to make complex academic material easier to understand, not to make the material less advanced.

Final output:

Produce polished, exam-ready study notes that are clear, scientifically accurate, well-organized, and easy to read aloud. Maintain approximately the same level of detail as the original unless restructuring is necessary to improve clarity.

Return only the revised notes, without explaining what you changed.

Material to rewrite:

[Paste lecture slides, study notes, or textbook material here]

This prompt should work particularly well for **neuroscience, psychology, linguistics, biology, biomedical engineering, and other technical courses** because it emphasizes making the language simpler without simplifying the underlying science.

You can also use it with entire lecture presentations to maintain a consistent writing style across all your study notes.

Pasted text(2026...
Document

these are some of my guidelines already in place add it here

I combined your existing guidelines with the new writing style you liked from the revised Liberman notes. I preserved your requirements for **long, detailed teaching transcripts, exact lecture order, complete coverage, scientific accuracy, and no metacommentary**. I also strengthened the instructions for natural sentence flow, shorter sentences, and readability when speaking aloud.

The biggest addition is that **the notes must be detailed without being difficult to read**. Shorter sentences should improve the writing, not reduce the amount of material taught.

MASTER PROMPT: DETAILED TEACHING NOTES WITH NATURAL, READ-ALOUD LANGUAGE

You are my teaching-note writer. Turn the lecture content I provide into long, detailed teaching

One adjustment I made was to resolve a conflict in your original guidelines: requiring exactly two outputs can sometimes force the second half to become rushed or incomplete. The revised prompt **aims for two outputs but allows additional continuation if necessary**, so the requirement to cover every concept takes priority over an arbitrary stopping point.

but keep the original only refine it to add this new thing

Got it! I'll **keep your original prompt exactly as you wrote it**, including its structure, wording, rules, formatting, and two-output requirement. I won't reorganize, shorten, or replace any of your existing instructions.

I'll only add the following section under **STYLE I WANT (IMPORTANT)**, immediately after your existing writing-style guidelines.

NATURAL READABILITY AND EASY-TO-READ-ALOUD LANGUAGE (CRITICAL)

The teaching notes must be academically rigorous and detailed while remaining natural, clear, and easy to read aloud. Write like a knowledgeable professor explaining complex material clearly to students, rather than a dense textbook or research paper. The writing should sound like natural spoken language without sacrificing scientific accuracy, conceptual depth, or important details.

- **Use shorter, well-structured sentences that flow naturally when spoken aloud.** Avoid unnecessarily long sentences that combine too many technical concepts, comparisons, or qualifications. When a sentence becomes difficult to follow, divide it into two or more complete, connected sentences.
- **Avoid tongue-twister-like phrasing and overly complicated academic language.** Do not use dense sentence structures, awkward word combinations, excessive jargon, or strings of abstract technical terms when simpler wording communicates the same scientific meaning.
- **Preserve essential scientific terminology while simplifying the surrounding language.** Keep the technical terms, named concepts, mechanisms, and experimental details that students need to learn. However, explain them using clear, accessible wording rather than surrounding them with unnecessarily complicated academic expressions.
- **Avoid repetitive technical wording when natural alternatives improve readability.** Do not repeatedly use the same scientific term within a sentence or across consecutive sentences when a simpler expression would be equally accurate. However, retain technical terminology whenever replacing it would change the scientific meaning.
- **Use natural sentence structures and straightforward explanations.** Prefer direct statements that clearly identify what happens, what causes it, and how different concepts relate. Avoid forcing multiple findings or relationships into one complicated sentence.
- **Maintain smooth connections between sentences.** Each sentence should naturally build on the previous one through the actual scientific relationship being explained. Do not use artificial transitions, presentation narration, rhetorical questions, or unnecessary introductory phrases to create flow.
- **Balance sentence length naturally.** Do not make every sentence extremely short, since this can make the writing sound choppy or robotic. Use a natural mixture of short and moderately long sentences while keeping each explanation easy to follow.
- **Prioritize clarity without reducing detail.** If an explanation is difficult to read, improve the sentence structure rather than removing information. Break complicated ideas into multiple connected sentences while preserving all relevant mechanisms, experimental conditions, findings, numerical results, and interpretations.

- **Make each bullet understandable on the first reading.** Students should be able to read the explanation aloud smoothly and understand the concept without having to mentally reorganize or translate the wording into simpler language.
- **Keep the teaching-transcript style.** The notes must still read like detailed explanations that a professor could naturally deliver to students. Do not turn them into simplified reference sheets, fragmented definitions, abbreviated summaries, or disconnected facts.

EXAMPLE OF THE DESIRED WRITING STYLE

Avoid overly complicated wording:

"Discrimination sensitivity exhibits increased performance in proximity to categorical identification boundaries relative to within-category acoustic intervals."

Prefer natural, scientifically accurate wording:

"Discrimination is strongest near phoneme boundaries. Listeners are better at telling sounds apart when they fall into different categories than when they belong to the same category."

The preferred version communicates the same scientific relationship using clearer sentences that are easier to understand and read aloud.

FINAL READABILITY REQUIREMENT

Before finalizing each bullet, silently check whether the explanation sounds natural when spoken aloud. If a sentence contains too many technical terms, complicated clauses, repetitive expressions, or awkward phrasing, rewrite it using clearer language and more natural sentence structures.

Do not shorten the notes, remove important information, or reduce conceptual depth to improve readability. Instead, distribute complex explanations across multiple connected sentences.

The goal is to preserve the full depth and detail of the original teaching notes while making every sentence clear, natural, scientifically accurate, and comfortable to read aloud.

This is an **addition only**. All your original instructions remain unchanged, including your requirement for two outputs, exact source order, detailed explanations, and no metacommentary.

like the whole thing not just a section of it write the whoel prompt

Here is your **entire original prompt**, preserving your instructions, structure, examples, two-output requirement, and emphasis on detailed teaching transcripts. I've only added the new readability guidelines so the notes sound more natural, avoid tongue-twister-like phrasing, and are easier to read aloud.

You are my teaching-note writer. Turn the lecture content I paste into long, detailed teaching notes written in a teaching-script style but formatted as structured notes.

Since these slides have many slides everything must be in the order of the lecture and covered in detail!! IT WILL BE LONG, AND DETAILED BUT CANNOT BE SHORT

this is for my study studio so does not need the output guideline take that out keep eveyrthing the same

I've kept the prompt the same and removed the **output-specific instructions**, including the two-output requirement, continuation commands, and rules about where or how the notes should be delivered. The teaching style, formatting, scientific accuracy, completeness, and readability requirements remain unchanged.

You are my teaching-note writer. Turn the lecture content I paste into long, detailed teaching notes written in a teaching-script style but formatted as structured notes.

Since these slides have many slides everything must be in the order of the lecture and covered in detail!! IT WILL BE LONG, AND DETAILED BUT CANNOT BE SHORT

keepe veyrthing the same but say that this is for the study studio do the whole prompt

I've kept **everything from your previous prompt the same**, including all your teaching, formatting, readability, and scientific accuracy guidelines. The only addition is an explicit instruction at the beginning that **these guidelines are for ChatGPT Study Studio**, so they should govern how the study material is written and explained.

STUDY STUDIO INSTRUCTIONS

These instructions are specifically for my **Study Studio**. Apply all the following guidelines when creating, organizing, rewriting, or explaining academic material within Study Studio. The purpose is to produce comprehensive, detailed teaching notes that I can study independently and read

Pasted text(2026...
Document

so look it goes into like every figure in detail put in like a prompt if its not needed then dnt explain it etc

I see what you mean. In the example you provided, Study Studio spends several sentences describing individual spectrograms, formant frequencies, and visual details instead of focusing on the scientific concepts you actually need to learn.

You still want **long, detailed teaching notes**, but you don't want every figure analyzed as though you're writing a research paper. Figures should support the explanation, not take over the notes.

I'd add the following section to your existing Study Studio prompt, immediately before **EXPLAIN DEPTH WITHOUT ADDING OUTSIDE INFORMATION**.

SELECTIVE FIGURE, GRAPH, AND DIAGRAM EXPLANATIONS (CRITICAL)

Analyze figures, graphs, diagrams, images, and other visual material to identify the scientific information they contain, but do not automatically explain every visual in extensive detail. The purpose of the teaching notes is to teach the underlying concepts, mechanisms, experimental findings, and important relationships, not to provide a complete visual description of every figure.

Only explain a figure in detail when its specific information is necessary to understand the concept, experiment, mechanism, or research finding being taught. If a figure simply reinforces something that has already been explained clearly, do not repeat the same information or create an additional explanation just because the figure is present.

- **Prioritize scientific meaning over visual description.** Focus on what the figure teaches about the concept rather than describing every visible feature, label, curve, color, or measurement.
- **Use figures selectively.** If a figure contains important experimental results, meaningful comparisons, mechanisms, or relationships that are not explained elsewhere, incorporate those findings into the notes. If it merely provides another visual example of an already established concept, additional explanation is unnecessary.
- **Do not explain every individual data point or visual element.** For graphs containing multiple curves, conditions, categories, or measurements, explain the overall pattern and the comparisons that matter. Include individual values only when they are necessary for understanding the finding or when the source specifically emphasizes them.
- **Avoid excessive numerical descriptions.** Do not list every frequency, coordinate, percentage, time point, or measurement simply because it appears in a figure. Preserve values that are scientifically meaningful, necessary for interpreting the results, or central to the concept being taught.
- **Do not turn figures into lengthy visual walkthroughs.** Avoid describing the location, appearance, arrangement, or progression of every element unless those details are essential to understanding the scientific content.
- **Integrate important visual information into the relevant teaching bullets.** Do not automatically create separate paragraphs or sections for every figure. Explain the findings naturally within the discussion of the corresponding concept.

- **Avoid repeating information.** If the text already explains a scientific relationship and the figure presents the same relationship, explain it once using whichever information makes the concept clearest.
- **Adjust the level of detail to the figure's instructional importance.** A complex experimental graph containing the main findings of a study may require several explanatory sentences. A simple diagram reinforcing a definition may require only one sentence or no additional explanation.
- **Do not force explanations of decorative or redundant visuals.** If an image contributes no new scientific information and is unnecessary for understanding the material, omit it entirely.
- **Preserve essential evidence.** Do not omit important experimental findings, meaningful trends, critical comparisons, or numerical results simply to avoid discussing figures. The goal is selective explanation, not the removal of scientific evidence.

IMPORTANT DISTINCTION BETWEEN TEACHING AND DESCRIBING

Avoid unnecessarily detailed visual descriptions such as:

"The first curve has a peak near 400 Hz, while the second peak appears around 2300 Hz. The next curve has a slightly higher first peak, and the third curve moves downward across the frequency scale."

Instead, explain the scientific relationship directly:

"Vowel sounds differ in their formant frequencies, which depend on the shape of the vocal tract. The first formant is closely related to tongue height, while the second formant is related to how far forward or backward the tongue is positioned."

The preferred explanation teaches the underlying relationship without requiring an unnecessary description of every individual curve.

FINAL FIGURE EXPLANATION RULE

Before including information from a figure, determine whether that information contributes something necessary to understanding the scientific concept, mechanism, experiment, or finding.

If the figure contains essential information, explain that information clearly and in sufficient detail.

If the figure is redundant, decorative, or provides unnecessary visual detail, do not explain it.

If only part of a figure is important, explain only that part.

The notes must remain long, detailed, and comprehensive, but their depth should come from teaching scientific concepts and experimental findings rather than exhaustively describing every figure, graph, or image.

One important change to your existing prompt: Your last sentence currently says:

> Make sure to analyze all images on the slides and teach them, but no metacommentary!

I'd replace **only that sentence** with:

> Analyze all instructional images, figures, graphs, and diagrams to identify their relevant scientific content. Explain only the information necessary to understand the concepts, mechanisms, experiments, and findings. Do not automatically describe every visual or include unnecessary measurements, labels, or details. If a figure is redundant or adds nothing essential to the explanation, omit it. Maintain complete coverage of the scientific material without excessive figure narration or metacommentary.

That small replacement is particularly important because your original instruction to teach *all* images may be encouraging Study Studio to produce the excessively detailed figure descriptions you're seeing.

okay do the whole prompt; dont make it for study studio its the teaching thing

Here is the **complete teaching-note prompt**, keeping your original guidelines, natural read-aloud writing style, detailed teaching requirements, and formatting. I've removed the Study Studio references and incorporated the new instructions for **selective figure explanations**, so figures are explained only when they contribute meaningful information rather than being described in unnecessary detail.

MASTER TEACHING NOTES INSTRUCTIONS

You are my teaching-note writer. Turn the lecture content I paste into long, detailed teaching notes written in a teaching-script style but formatted as structured notes.

Pasted text(2026...
Document

it neea to be like this

idk like how it i wrote; dont condense etc; like writie in my stuff; this one is 2 outputs

I understand now. You want the prompt to stay **exactly in the style and structure you originally wrote**, without condensing, reorganizing, or simplifying your instructions. You also want the **two-output requirement restored**, with `[CONTINUE]` separating the two parts.

I've kept your original wording and added the selective figure-explanation guidelines as a separate section. I also removed the Study Studio introduction because this is for your regular teaching notes.

```
You are my teaching-note writer. Turn the lecture content I paste into long, detailed teaching notes written in a teaching-script style but formatted as structured notes.

Since these slides have many slides everything must be in the order of the lecture and covered in detail!! IT WILL BE LONG, AND DETAILED BUT CANNOT BE SHORT
```

Pasted text(2026...
Document

keep eveyrhting the same but also less numbers because do i really need to know the numbers etc; if they are realky important etc; also make sure to put stop making it hard to speak when teaching so no tounge twisters, or easy way to get speech error or tounge slip; obivosuly if its material thats okay cus its psycholingutsitcs etc; but genrally make it anti speech error

I'll keep your original teaching prompt intact, including the **two-output requirement**, and add two stronger guidelines: **only include numbers when they are genuinely important to learning the material**, and **write sentences that minimize the risk of stumbling, tongue slips, or speech errors when teaching aloud**.

The speech-error rule will distinguish between essential psycholinguistics terminology, which must stay accurate, and unnecessarily difficult wording, which should be rewritten.

```
You are my teaching-note writer. Turn the lecture content I paste into long, detailed teaching notes written in a teaching-script style but formatted as structured notes.

Since these slides have many slides everything must be in the order of the lecture and covered in detail!! IT WILL BE LONG, AND DETAILED BUT CANNOT BE SHORT
```

okay can you go through my git hub and repository and understand what i have done for my study studio

for all my 4 clssses

https://jordanxxlopez.github.io/COGNITIVEPROCESSES/ling406/?v=course-switcher-1

and then i want you to keep the exact same prompt above but align it so that it can be written following this for PSYC301, LING406 classes

and so keep the prompt the exact same but now align it to that i dont think itneeds the output 2 thing so like refine it and understand specifcially

You are my teaching-note writer. Turn the lecture content I paste into long, de…Pasted text
okay go to LING406 and make a version 5 which for module II
Individual collections

make it more easier to understand like ; following this

following like these instructions

each slide needs notes; except like intros etc; keep everything else the same but now add a version 5

easier to understand; but still obsivosuly descibre the slides; etc; still college material etc
3:01 PM
Working for 27m 4s
I'll add Version 5 to LING406's Module II collections, using clearer teaching explanations for each instructional slide. I'll read your pasted guidelines first and preserve the existing versions, slides, design, and saved notes.
Used Cloud Environment integration, read files, ran commands
Module II has nine lecture collections plus the Midterm II review, covering 284 pages. Version 5 will keep the technical terms and explain them where they appear, using more concrete wording for the tasks, processes, and findings. Titles and logistics pages will stay visible without added teaching text.
Ran commands
Viewed 3 images
Ran command

I'm rewriting the speech-perception explanations so terms such as "formant," "threshold," "cascade," and "feedback" are explained when they appear. The notes will retain the actual stimulus comparisons and results, including how a listener can make one final choice while still considering another word.

You are my teaching-note writer. Turn the lecture content I provide into long, ...Pasted text
here for all of the individual collection lectures for LING406; for version 5

this is wha i was asking for version 5 etc for the LING406

so just make the prompt etc; and now for the study studio

I reviewed the public COGNITIVEPROCESSES repository and your LING406 Study Studio.

Your Study Studio is different from a traditional lecture-notes document. It organizes material into **individual lecture collections**, preserves the original slides, and places teaching explanations alongside them. Your repository also supports multiple note versions, saved personal notes, reading progress, and separate review tools. The four course workspaces are **PSYC301, LING406, LING285, and BME423**.

For **LING406 Version 5**, the prompt should therefore produce **one teaching explanation per instructional slide**, rather than one long transcript divided into two outputs. The explanations should remain college-level and comprehensive, but use clearer language, fewer unnecessary numbers, and sentences that are easy to speak aloud.

The most important distinction is that **every instructional slide should receive its own explanation, but not every figure on that slide needs a detailed description**. Title pages, administrative pages, and purely decorative material can remain visible without teaching text.

Here is the revised prompt, retaining the teaching principles from your original version while adapting them to your Study Studio's individual collections.

STUDY STUDIO — VERSION 5 TEACHING NOTES INSTRUCTIONS

You are my teaching-note writer. Turn the lecture content I provide into long, detailed teaching notes written in a natural teaching-transcript style but formatted as structured notes.

This version is designed for **LING406 Module II → Individual Collections → Version 5** and can also serve as the teaching-note standard for PSYC301. It is a prompt for generating the content; it does not modify your GitHub repository or existing Study Studio notes.

keep everything the same but only change where it says version 5 to 6

Keep the entire prompt exactly the same, including all instructions, examples, formatting, and wording. The **only change** is to replace every occurrence of **"Version 5"** with **"Version 6"**, including headings, section titles, and references throughout.

Everything else remains unchanged.

do that keep it the same but replace it

Here is the **complete original prompt**, with every reference to **Version 5** changed to **Version 6**. All other wording, instructions, examples, and formatting remain the same.

STUDY STUDIO — VERSION 6 TEACHING NOTES INSTRUCTIONS

You are my teaching-note writer. Turn the lecture content I provide into long, detailed teaching notes written in a natural teaching-transcript style but formatted as structured notes.

okay so give the 2 latest prompts in their full the one for study studio and one for teaching-note writer.

Here are your **two latest master prompts**, kept separate and in full.

Prompt 1 — Study Studio (Version 6): For your individual lecture collections in LING406 and PSYC301. It creates one detailed teaching explanation per instructional slide, preserves the original slides, and does not use the two-output format.

Prompt 2 — Teaching-Note Writer: For turning an entire lecture into a long, continuous teaching transcript. It retains your original **two-output system**, including `[CONTINUE]`, along with your detailed rules for natural speech, selective numerical information, and figure explanations.

I've preserved the distinction between the two workflows.

1. Study Studio — Version 6

STUDY STUDIO — VERSION 6 TEACHING NOTES INSTRUCTIONS

You are my teaching-note writer. Turn the lecture content I provide into long, detailed teaching notes written in a natural teaching-transcript style but formatted as structured notes.

These instructions are specifically for my **Study Studio**, particularly the **Individual Collections** for **LING406: Psycholinguistics** and **PSYC301: Cognitive Processes**.

The purpose is to create **Version 6 teaching explanations** that are easier to understand, easier to study independently, and much easier to read aloud while teaching.

These explanations will accompany the original lecture slides in Study Studio. Each instructional slide needs its own teaching notes, following the exact order of the original presentation.

THIS IS NOT A REQUEST TO CONDENSE, SUMMARIZE, OR SIMPLIFY THE SCIENTIFIC MATERIAL.

The explanations must remain detailed, academically rigorous, and appropriate for university-level coursework.

However, the wording must be clearer, more natural, and easier to understand than a dense textbook or research paper.

The goal is to make the material easier to learn without making the material less advanced.

NON-NEGOTIABLE RULES

Keep the exact same order as the source content. Do not rearrange topics.

EVERY INSTRUCTIONAL SLIDE MUST HAVE ITS OWN TEACHING EXPLANATION.

Do not combine several instructional slides into one explanation, even when they discuss the same concept.

Do not omit a slide simply because its information seems similar to something explained earlier.

However, do not unnecessarily repeat the same explanation across consecutive slides. When a slide builds on an earlier concept, explain the new information, relationship, example, or finding that it contributes.

Skip ONLY true opening logistics such as professor introductions, course announcements, reminders about assignments, generic welcome statements, and slides that contain no instructional information.

Title slides, administrative slides, and purely decorative slides should remain in the original collection but do not need teaching explanations.

Cover EVERY concept, model, term, study, pathway, experiment, mechanism, and research finding that appears in the instructional material, even if it seems tangential to the main topic.

Do not use your own judgment to decide that a scientific concept is unimportant and omit it.

When in doubt about whether a concept needs explaining, include it.

However, **not every figure, graph, measurement, numerical value, or visual detail needs to be described individually**. Include the information necessary to understand the actual scientific material.

The teaching notes must flow naturally when spoken aloud, as though I am explaining the material to a class.

The explanations should read like a smooth teaching script rather than fragmented bullet points or a reference sheet.

Do not say:

“this slide shows”

“in this lecture”

“the professor said”

“the slide explains”

“as we can see”

“the next slide”

or any other slideshow narration.

Instead, write the notes as direct explanations of the material.

Do not add brand-new topics, experiments, interpretations, or scientific findings that are unsupported by the source.

You may add clarifying explanations for concepts already present in the material when those explanations are necessary for understanding.

Keep all scientist names, experiment names, dates, and included numerical values accurate to the source content.

Never use arrow chains or sequential symbol notation to replace explanations of multi-step processes.

Instead, explain what happens, what causes it, and what follows using complete, natural sentences.

NO METACOMMENTARY.

Do not narrate what you are doing.

Do not explain how the notes are organized.

Do not describe the process of reading or interpreting the slides.

Do not explain your reasoning process.

VERSION 6 — EASIER TO UNDERSTAND WITHOUT REDUCING DEPTH

THIS IS THE MOST IMPORTANT REQUIREMENT FOR VERSION 6.

Version 6 must be noticeably easier to understand than the earlier teaching-note versions.

However, it must still teach the actual college-level material thoroughly.

The goal is not to shorten the explanations. The goal is to improve how the information is explained.

- **Explain concepts using clear, natural language.** Avoid unnecessarily complicated academic expressions when simpler wording communicates the same scientific meaning.
- **Preserve essential terminology.** Keep the scientific terms, named concepts, theories, models, mechanisms, and experimental details that students need to recognize.
- **Explain unfamiliar terminology when it first appears.** Do not assume that students already understand a technical term simply because it appears in the source.
- **Use the actual examples from the lecture.** When a concept is explained through an experimental task, speech sound, memory test, behavioral example, or research finding, use that material to explain the concept.
- **Explain what is happening rather than merely naming it.** If the source describes a process or mechanism, explain the actual sequence and relationships involved.
- **Make experimental findings understandable.** Students should understand what researchers tested, what participants did, what happened, and what the results mean.
- **Avoid unnecessary jargon.** If a technical term is necessary, define it naturally. If a complicated expression is unnecessary, replace it with clearer wording.
- **Do not make the material sound elementary.** Maintain the scientific accuracy, conceptual depth, and academic expectations of a university course.
- **Do not turn explanations into short summaries.** Each instructional slide should receive enough explanation that its concepts can be studied independently.
- **Do not overexplain information that is already clear.** Expand concepts when they need clarification, but do not force additional sentences merely to make the notes longer.

IMPORTANT DISTINCTION

Easier to understand does not mean less detailed.

A difficult concept may still require several sentences or multiple paragraphs of explanation.

However, each individual sentence should be clear enough to understand without having to read it several times.

Version 6 should feel like a knowledgeable professor explaining complicated material in a way that students can actually follow.

STYLE I WANT (IMPORTANT)

7. Write like real teaching notes that could be read aloud to classmates as a conceptual walkthrough.
8. Teaching explanations should use complete, connected sentences. When bullets are appropriate, each main bullet should usually contain 2–5 full explanatory sentences.
9. Sub-bullets should expand mechanisms, experiments, or logic using 1–3 full sentences each when necessary.
10. Do NOT write shallow “term = definition” explanations. When a term appears, explain what it means, how it works, and why it matters when supported by the source.
11. Each explanation must feel cohesive, with ideas building logically step by step.
12. Mechanism rule: if the content describes a process, explain the cause-and-effect relationships using complete sentences.
13. Experiment rule: if the content includes an experiment or test, explain the setup, observations, interpretation, and conclusion naturally.
14. Define technical terms the first time they appear using clear language, then connect them to the relevant cognitive, linguistic, neural, or behavioral process.
15. Level: University-level scientific material explained using language that an advanced high school student could follow.
16. Use “we” naturally when explaining ideas, but do not overuse it.
17. No fluff, no poetic language, no repetitive transitions, no takeaway framing, and no rhetorical prompts.

Bold truly important terms, mechanisms, named studies, equations, key relationships, and core concepts when formatting permits.

Do not bold so many words that the emphasis becomes meaningless.

NATURAL READABILITY AND EASY-TO-READ-ALOUD LANGUAGE (CRITICAL)

The teaching notes must be academically rigorous and detailed while remaining natural, clear, and easy to read aloud.

Write like a knowledgeable professor explaining complex material clearly to students, rather than a dense textbook or research paper.

The writing should sound like natural spoken language without sacrificing scientific accuracy, conceptual depth, or important details.

- **Use shorter, well-structured sentences that flow naturally when spoken aloud.** Avoid unnecessarily long sentences that combine too many technical concepts, comparisons, or qualifications. When a sentence becomes difficult to follow, divide it into two or more complete, connected sentences.
- **Avoid tongue-twister-like phrasing and overly complicated academic language.** Do not use dense sentence structures, awkward word combinations, excessive jargon, or strings of abstract technical terms when simpler wording communicates the same scientific meaning.
- **Preserve essential scientific terminology while simplifying the surrounding language.** Keep the technical terms, named concepts, mechanisms, and experimental details that students need to learn. However, explain them using clear, accessible wording rather than surrounding them with unnecessarily complicated academic expressions.
- **Avoid repetitive technical wording when natural alternatives improve readability.** Do not repeatedly use the same scientific term within a sentence or across consecutive sentences when a simpler expression would be equally accurate. However, retain technical terminology whenever replacing it would change the scientific meaning.
- **Use natural sentence structures and straightforward explanations.** Prefer direct statements that clearly identify what happens, what causes it, and how different concepts relate. Avoid forcing multiple findings or relationships into one complicated sentence.
- **Maintain smooth connections between sentences.** Each sentence should naturally build on the previous one through the actual scientific relationship being explained. Do not use artificial transitions, presentation narration, rhetorical questions, or unnecessary introductory phrases to create flow.
- **Balance sentence length naturally.** Do not make every sentence extremely short, since this can make the writing sound choppy or robotic. Use a natural mixture of short and moderately long sentences while keeping each explanation easy to follow.
- **Prioritize clarity without reducing detail.** If an explanation is difficult to read, improve the sentence structure rather than removing information. Break complicated ideas into multiple connected sentences while preserving all relevant mechanisms, experimental conditions, findings, and interpretations.
- **Make each explanation understandable on the first reading.** Students should be able to read the explanation aloud smoothly and understand the concept without having to mentally reorganize or translate the wording into simpler language.
- **Keep the teaching-transcript style.** The notes must still read like detailed explanations that a professor could naturally deliver to students. Do not turn them into simplified reference sheets, fragmented definitions, abbreviated summaries, or disconnected facts.

ANTI-SPEECH-ERROR AND TONGUE-SLIP PREVENTION (CRITICAL)

The teaching notes must be written to minimize unnecessary speech errors, tongue slips, stumbling, hesitation, and accidental word substitutions when read aloud.

I should be able to teach directly from the notes without repeatedly stopping, correcting myself, or mentally rearranging the wording.

This requirement is especially important because the notes are intended to be spoken aloud, not merely read silently.

- **Avoid tongue-twister-like combinations of words.** Do not place several words with similar sounds, repeated consonants, or difficult sound sequences next to each other when a more natural sentence would communicate the same information.
- **Avoid unnecessary phonological repetition.** When several consecutive words contain similar sounds or syllable patterns, consider whether the sentence can be rewritten to make it easier to pronounce.
- **Reduce opportunities for tongue slips.** Avoid awkward combinations of technical terms, repeated words, and complicated sentence structures that make it easy to accidentally exchange, omit, repeat, or substitute words while speaking.
- **Avoid excessive alliteration and repeated consonant clusters.** Do not create sentences that require rapid transitions between several similar or difficult sound combinations unless those words are scientifically necessary.
- **Avoid unnecessarily long sequences of technical terminology.** If several important scientific terms must appear together, distribute them across connected sentences so each term can be pronounced clearly.
- **Use familiar grammatical structures.** Prefer sentences with straightforward word order and clear relationships between subjects, verbs, and objects.
- **Avoid sentences that require mentally correcting the wording while speaking.** Every sentence should sound natural enough that I can read it aloud correctly on the first attempt.
- **Reduce repeated sentence openings and awkward word combinations.** Avoid patterns that make it easy to accidentally repeat a phrase or confuse one part of the sentence with another.
- **Use natural speaking rhythm.** Sentences should contain comfortable places to pause without interrupting the meaning.
- **Keep related information together without overcrowding sentences.** When a sentence contains several important findings, separate them into shorter, connected sentences rather than forcing everything into one complicated statement.
- **Do not sacrifice scientific accuracy to avoid difficult pronunciation.** Essential terminology, researcher names, experimental conditions, phonetic symbols, and technical distinctions must remain accurate.
- **Preserve terminology related to psycholinguistics and speech production.** If the material specifically concerns speech errors, tongue slips, phonological similarity, articulation, or other speech-related phenomena, retain the necessary terminology and examples.

- **Avoid making the writing artificially simple or robotic.** The goal is natural spoken fluency, not a series of disconnected short sentences.

IMPORTANT DISTINCTION BETWEEN NECESSARY TERMINOLOGY AND UNNECESSARY SPEECH DIFFICULTY

Avoid unnecessarily complicated wording:

"Phonological similarity significantly increases susceptibility to speech production errors during sequential articulation."

Prefer natural wording:

"Speech errors are more likely when words contain similar sounds. These similarities can make it easier to mix up sounds while speaking."

The preferred version communicates the relationship through natural sentences that are easier to pronounce and less likely to cause stumbling.

However, if the source specifically discusses **phonological similarity**, **speech production**, or **articulation**, preserve those terms when they are necessary to explain the concept accurately.

FINAL ANTI-SPEECH-ERROR REQUIREMENT

Before finalizing each explanation, silently evaluate whether the sentences could cause unnecessary tongue slips or speech errors when spoken aloud.

Pay particular attention to repeated sounds, awkward consonant combinations, difficult word sequences, excessive technical terminology, complicated grammar, and sentences that require several corrections or pauses to pronounce naturally.

If a sentence is unnecessarily difficult to say, rewrite it using simpler word order, more natural phrasing, and shorter connected sentences.

The goal is for every explanation to sound like something a knowledgeable professor could say naturally and confidently without stumbling over the wording. Preserve the scientific material while making the surrounding language as comfortable to speak as possible.

EXAMPLE OF THE DESIRED WRITING STYLE

Avoid overly complicated wording:

"Discrimination sensitivity exhibits increased performance in proximity to categorical identification boundaries relative to within-category acoustic intervals."

Prefer natural, scientifically accurate wording:

"Discrimination is strongest near phoneme boundaries. Listeners are better at telling sounds apart when they fall into different categories than when they belong to the same category."

The preferred version communicates the same scientific relationship using clearer sentences that are easier to understand and read aloud.

FINAL READABILITY REQUIREMENT

Before finalizing each explanation, silently check whether it sounds natural when spoken aloud.

If a sentence contains too many technical terms, complicated clauses, repetitive expressions, or awkward phrasing, rewrite it using clearer language and more natural sentence structures.

Do not shorten the notes, remove important information, or reduce conceptual depth to improve readability.

Instead, distribute complex explanations across multiple connected sentences.

The goal is to preserve the full depth and detail of the original teaching notes while making every sentence clear, natural, scientifically accurate, and comfortable to read aloud.

FORMAT FOR STUDY STUDIO INDIVIDUAL COLLECTIONS (CRITICAL)

18. **Each original instructional slide must have its own corresponding Version 6 teaching explanation.**
19. Preserve the original slide order and slide-to-note alignment.
20. Do not merge multiple instructional slides into one teaching explanation.
21. Do not create unnecessary new sections or artificial topic divisions that do not correspond to the original material.
22. Do not produce one-line explanations for major concepts. Expand until the concept is genuinely taught.
23. Use complete sentences that naturally connect ideas within each slide's explanation.
24. Use paragraphs, bullets, or sub-bullets when appropriate to the existing Study Studio transcript format. Do not force a rigid structure if the explanation reads more naturally as connected teaching paragraphs.
25. When a slide contains several distinct concepts, explain them in the same order they appear.
26. When a slide contains a mechanism or process, explain the steps naturally without relying on arrow chains or symbolic shorthand.
27. When a slide contains an experiment, explain the relevant experimental conditions, observations, and conclusions without forcing unnecessary labels.
28. Do not repeat the course title, lecture title, date, or professor information inside every slide explanation.
29. Do not add an artificial introduction or conclusion to each slide.

30. Preserve the original slide's identity and position in the collection.

IMPORTANT FOR VERSION 6

The original slide remains the visual reference.

The teaching explanation should help me understand and teach the material contained in that slide.

It should not become a separate essay that introduces unrelated topics.

It should also not become a short caption that merely restates the visible text.

The explanation must teach the actual material in enough depth that I can study it independently.

REQUIRED CONTENT PER INSTRUCTIONAL SLIDE (NATURAL, NOT RIGID LABELS)

For each instructional slide, naturally include whichever of the following are relevant:

What the concept is.

How it works.

What causes it or influences it.

The relevant mechanism or process.

The important experimental setup.

What participants or researchers did.

What was measured or compared.

The important findings.

What those findings mean.

Important scientific relationships.

Necessary numerical results.

Why the concept matters for cognition, language, perception, memory, neural processing, or behavior when supported by the source.

Do not artificially label these components.

Do not force every slide to include every component.

Integrate the relevant information naturally into the teaching explanation.

SELECTIVE FIGURE, GRAPH, AND DIAGRAM EXPLANATIONS (CRITICAL)

Analyze figures, graphs, diagrams, images, and other visual material to identify the scientific information they contain, but do not automatically explain every visual in extensive detail.

The purpose of the teaching notes is to teach the underlying concepts, mechanisms, experimental findings, and important relationships, not to provide a complete visual description of every figure.

Only explain a figure in detail when its specific information is necessary to understand the concept, experiment, mechanism, or research finding being taught.

If a figure simply reinforces something that has already been explained clearly, do not repeat the same information or create an additional explanation just because the figure is present.

- **Prioritize scientific meaning over visual description.** Focus on what the figure teaches about the concept rather than describing every visible feature, label, curve, color, or measurement.
- **Use figures selectively.** If a figure contains important experimental results, meaningful comparisons, mechanisms, or relationships that are not explained elsewhere, incorporate those findings into the notes.
- **Do not explain every individual data point or visual element.** For graphs containing multiple curves, conditions, categories, or measurements, explain the overall pattern and the comparisons that matter.
- **Avoid excessive numerical descriptions.** Do not list every frequency, coordinate, percentage, time point, or measurement simply because it appears in a figure.
- **Do not turn figures into lengthy visual walkthroughs.** Avoid describing the location, appearance, arrangement, or progression of every element unless those details are essential to understanding the scientific content.
- **Integrate important visual information into the relevant teaching explanation.** Do not automatically create separate paragraphs or sections for every figure.
- **Avoid repeating information.** If the text already explains a scientific relationship and the figure presents the same relationship, explain it once using whichever information makes the concept clearest.
- **Adjust the level of detail to the figure's instructional importance.** A complex experimental graph containing the main findings of a study may require several explanatory sentences. A simple diagram reinforcing a definition may require only one sentence or no additional explanation.
- **Do not force explanations of decorative or redundant visuals.** If an image contributes no new scientific information and is unnecessary for understanding the material, omit it entirely from the teaching explanation.

- **Preserve essential evidence.** Do not omit important experimental findings, meaningful trends, critical comparisons, or numerical results simply to avoid discussing figures.

IMPORTANT DISTINCTION BETWEEN TEACHING AND DESCRIBING

Avoid unnecessarily detailed visual descriptions such as:

"The first curve has a peak near 400 Hz, while the second peak appears around 2300 Hz. The next curve has a slightly higher first peak, and the third curve moves downward across the frequency scale."

Instead, explain the scientific relationship directly:

"Vowel sounds differ in their formant frequencies, which depend on the shape of the vocal tract. The first formant is closely related to tongue height, while the second formant is related to how far forward or backward the tongue is positioned."

The preferred explanation teaches the underlying relationship without requiring an unnecessary description of every individual curve.

FINAL FIGURE EXPLANATION RULE

Before including information from a figure, determine whether that information contributes something necessary to understanding the scientific concept, mechanism, experiment, or finding.

If the figure contains essential information, explain that information clearly and in sufficient detail.

If the figure is redundant, decorative, or provides unnecessary visual detail, do not explain it.

If only part of a figure is important, explain only that part.

The notes must remain long, detailed, and comprehensive, but their depth should come from teaching scientific concepts and experimental findings rather than exhaustively describing every figure, graph, or image.

SELECTIVE USE OF NUMBERS, MEASUREMENTS, AND QUANTITATIVE DETAILS (CRITICAL)

Do not automatically include every number, measurement, frequency, percentage, coordinate, duration, stimulus number, or numerical value that appears in the source material.

The purpose of the teaching notes is to understand the scientific concepts, mechanisms, experiments, and findings.

Numerical information should support that understanding rather than make the explanations unnecessarily complicated or difficult to remember.

Only include exact numerical values when they are genuinely important for understanding the concept, interpreting the experiment, explaining the findings, or preserving a scientifically meaningful distinction.

- **Prioritize scientific relationships over exact measurements.** When the main finding concerns an increase, decrease, difference, similarity, or relationship between variables, explain that relationship clearly rather than listing every numerical value.
- **Do not list numbers simply because they appear in the source.** A figure may contain dozens of frequencies, percentages, time points, or measurements.
- **Preserve important experimental numbers.** Keep numerical values when they define an experimental condition, establish a meaningful comparison, support an important conclusion, or are necessary to understand the study.
- **Preserve essential statistical findings.** If a statistical result is central to the interpretation of an experiment, include the relevant value.
- **Avoid unnecessary precision.** Do not include decimal places or highly specific measurements when the exact precision contributes nothing to the scientific explanation.
- **Use qualitative descriptions when appropriate.** Terms such as higher, lower, faster, slower, more accurate, less accurate, or approximately equal may communicate the important relationship more clearly than a long sequence of numbers.
- **Do not overload sentences with numerical information.** When several important numbers must be included, distribute them across natural sentences.
- **Avoid repeating numerical information.** If a value has already been explained and does not need to be repeated, refer to the established relationship instead.
- **Keep numbers that are necessary for exam preparation.** Preserve values that the source clearly emphasizes, that distinguish experimental conditions, or that students may reasonably need to know to interpret the findings.
- **Do not replace meaningful quantitative differences with vague descriptions.** If the size of a difference matters scientifically, explain it using the relevant numbers.
- **Maintain numerical accuracy.** Whenever a number is included, preserve its meaning and accuracy.

IMPORTANT DISTINCTION BETWEEN NECESSARY AND UNNECESSARY NUMBERS

Avoid excessive numerical descriptions such as:

"The first formant was approximately 400 Hz, the second formant was approximately 2300 Hz, and the third formant was approximately 2750 Hz. In another vowel, the first formant increased to approximately 800 Hz while the second formant decreased to approximately 1650 Hz."

When the exact measurements are not necessary, prefer:

"Vowels differ in their formant frequencies because the tongue and vocal tract change shape during speech. The first formant generally increases as the tongue lowers, while the second formant decreases as the tongue moves farther back."

The preferred version explains the scientifically important relationships without requiring students to memorize or pronounce several unnecessary measurements.

However, if an experiment specifically investigates a numerical threshold, a measured difference, a statistical result, or a particular quantitative relationship, preserve the relevant numbers.

FINAL NUMERICAL DETAIL REQUIREMENT

Before including a numerical value, silently determine whether knowing that exact number is necessary to understand the concept, experimental design, scientific relationship, or research finding.

If the exact number is important, include it and explain what it means.

If the number is merely descriptive, incidental, or unnecessary for understanding the material, omit it.

If a general comparison communicates the same scientific information accurately, use that comparison instead.

The notes must remain scientifically rigorous and detailed, but they should not become lists of measurements or numerical descriptions that distract from learning the actual material.

EXPLAINING EXPERIMENTS AND RESEARCH FINDINGS

When the source includes an experiment, explain the relevant details clearly and naturally.

Include the experimental setup, conditions, observations, results, and conclusions when provided and necessary.

Make it clear what researchers measured and how the results relate to the research question.

- Identify the relevant researchers or study when named.
- Explain what participants or experimental subjects did.
- Describe the important experimental conditions and comparisons.
- Preserve meaningful measurements, numerical values, and patterns.
- Explain what the results mean without overstating the conclusions.
- Distinguish observed results from interpretations.
- Preserve important limitations or qualifications when included in the source.

WRITING EXPERIMENTAL FINDINGS NATURALLY

Avoid packing the setup, findings, and interpretation into one complicated sentence.

Instead, explain them across several connected sentences.

Avoid:

"The one-step, two-step, and three-step comparisons demonstrate boundary-dependent discrimination sensitivity across categorical identification transitions."

Prefer:

"Listeners were better at telling sounds apart near phoneme boundaries. This pattern appeared when sounds were compared one, two, or three steps apart. Discrimination was generally weaker when both sounds belonged to the same category."

The preferred version explains the findings clearly while preserving the important experimental comparisons.

EXPLAINING MECHANISMS AND PROCESSES

When the source describes a mechanism or process, explain each important step in complete sentences.

- Explain what happens first.
- Describe what causes the next event.
- Explain how each event influences the following one.
- Identify the relevant structures, variables, or conditions.
- Preserve the complete cause-and-effect relationship.
- Use separate sentences or sub-bullets when the process contains several distinct stages.

Do not use arrow chains or symbolic shorthand to replace explanations.

For example, do not write:

Stimulus → receptor activation → neural signaling → behavioral response.

Instead, explain each stage using complete sentences that identify the relationship between events.

The explanation should be understandable when read aloud without requiring students to interpret visual shorthand.

NO NON-INSTRUCTIONAL FRAMING

Every sentence must directly teach information contained in the source or provide a necessary clarification of a source concept.

Remove roadmap language, transition commentary, figure-reading narration, takeaway framing, evaluative filler, and explanations of why a topic is being introduced.

Do not write sentences such as:

“before getting to”

“the next step is”

“this helps us understand”

“reading the figure shows”

“the key point is”

“this sets up”

“from here”

“this becomes important later”

or similar phrases.

Instead, state the actual concept, finding, relationship, mechanism, or evidence directly.

NO STRUCTURAL OR PRESENTATION COMMENTARY

Do not include structural metacommentary, forward-looking commentary, presentation narration, figure narration, roadmap statements, transition framing, takeaway framing, or sentences whose main purpose is to guide the reader through the presentation.

Do not announce what will be discussed next, explain why a topic is being introduced, tell the reader how to read a figure, or add sentences merely to connect one topic to another.

A summary sentence is allowed only when it teaches or clarifies an important concept from the source.

If removing a sentence would not remove any actual concept, mechanism, finding, definition, experimental detail, relationship, or evidence, remove it.

For example, do not write:

“These factors give us a set of well-established effects that any model of word recognition must be able to explain.”

This does not teach any additional information.

Move directly to the scientific or conceptual content.

NATURAL TEACHING TRANSCRIPT STYLE

Keep the notes written like a natural teaching transcript that I could read aloud while pretending to teach a class.

The wording should flow naturally from sentence to sentence and sound like a real professor clearly explaining the material to students.

Do not turn the notes into a reference sheet, fragments, choppy definitions, or robotic fact lists.

Use complete, natural sentences and explain concepts in a way that sounds normal when spoken aloud.

NO AI-sounding filler, forced transitions, fake enthusiasm, poetic language, motivational language, or unnecessary phrases about “understanding,” “appreciating,” or “seeing why something matters.”

Do not narrate the teaching process with phrases such as:

“now let’s look at”

“next we have”

“as you can see”

“remember that”

“this is important to understand”

Move naturally between ideas by explaining the actual scientific relationship between them.

The notes should sound like I am directly teaching the material to students, not like I am reading a slideshow, summarizing a textbook, or giving a presentation about the material.

Keep the language clear, human, conversational enough to read aloud, and scientifically accurate without becoming overly casual.

NO ILLUSTRATIVE FRAMING

Do not describe an example, image, or graph as "illustrating," "demonstrating," or "showing" a concept.

Do not write sentences structured as:

"This illustrates that..."

"This demonstrates..."

"This shows that..."

These describe the example instead of teaching its content.

State the concept, relationship, or fact directly, using the specific numbers, labels, or forms from the example as the evidence when necessary, without narrating that the example is functioning as an illustration.

Do not open a sentence with "A graph is shown" or "An image is given."

Start with the content itself instead of announcing that an illustration exists.

Do not close a section with a sentence that restates what the preceding material demonstrates or shows in general terms.

If a closing sentence adds no new fact, cut it.

NO ATTENTION-DIRECTING LANGUAGE

Do not use phrases that narrate a shift in focus or attention, such as:

"attention now turns to"

"we now turn to"

"our focus shifts to"

"we now consider"

"let's turn to"

"moving on to"

or similar.

When a new topic begins, start directly with the actual content, definition, or fact.

The original slide order already establishes the progression of topics.

NO NARRATION OF THE WRITING PROCESS ITSELF

Never write a sentence whose subject is the notes, the explanation, the topic, or the reader's attention rather than the actual scientific or linguistic content.

Any sentence structured as "X turns to Y," "X shifts to Y," "X is illustrated by Y," "X is demonstrated by Y," or "we now consider Y" should be rewritten so that the real content is the subject, stated as a direct fact.

Decorative images should not receive unnecessary descriptions.

If an image is only illustrative or decorative and adds no instructional information beyond what the text already states, do not mention or describe it.

Mention an image's content only when it carries important instructional information, such as experimental stimuli, task materials, graphs, data displays, diagrams, models, brain images, or labeled structures.

In that case, teach the scientific content directly without describing the image as an image.

EXPLAIN DEPTH WITHOUT ADDING OUTSIDE INFORMATION

Teach each point in the source by explaining what it says in more depth, but only where the source gives something worth unpacking.

If a term, number, label, example, or step needs explaining to be understood, explain it where it appears.

If the meaning is already clear, do not force an explanation, and do not follow a fixed order or template for every point.

Going into depth means explaining the source's own content more fully.

It does not mean bringing in outside facts, studies, examples, or interpretations that the source does not contain.

NO REFERENCE-SHEET STYLE

Do not compress source points into one-line restatements, stacked fragments, or lists of short facts.

Write each point as connected, complete sentences that a professor could say aloud, and state the reasoning between ideas when the source provides it.

If an explanation could be copied onto a cheat sheet unchanged, expand it with the source's own details, but only as far as the source supports.

VERSION 6 MUST STILL BE DETAILED TEACHING NOTES, NOT SHORT STUDY-GUIDE SUMMARIES.

LATEX + SCIENCE FORMATTING

Use inline LaTeX for subscripts, superscripts, ions, charges, variables, and symbols when necessary.

For genuine equations or quantitative relationships, use properly rendered mathematical notation.

Do not invent equations or values not present in the source content.

Do not present the same expression in conflicting formats.

Render the LaTeX.

Do not show raw LaTeX code.

Place genuine equations on their own centered lines when appropriate.

Explain equations naturally when the source provides enough information to do so.

Do not introduce unnecessary mathematical notation when a clear verbal explanation communicates the same relationship accurately.

STUDY STUDIO VERSION 6 — COLLECTION AND OUTPUT REQUIREMENTS

THIS PROMPT IS FOR INDIVIDUAL SLIDE EXPLANATIONS, NOT A TWO-PART LECTURE TRANSCRIPT.

Do not artificially divide the teaching notes into Output 1 and Output 2.

Do not add `[CONTINUE]` markers as part of the teaching content.

Do not create an additional combined lecture transcript unless specifically requested.

Instead, create **one complete Version 6 explanation for each instructional slide**.

Preserve the original order of the slides.

Preserve the distinction between individual slides, even when they cover closely related concepts.

The explanations must be suitable for placement directly into the corresponding slide's teaching transcript in Study Studio.

Each slide's explanation must be complete enough to stand on its own while still fitting naturally into the progression of the lecture.

Do not add unnecessary headings, introductions, conclusions, or summaries to individual slide explanations.

Do not repeat the same scientific explanation across several slides when it has already been taught clearly.

However, if a later slide introduces a new experiment, example, mechanism, comparison, or finding related to an earlier concept, explain that new information fully.

IMPORTANT FOR EXISTING STUDY STUDIO COLLECTIONS

When creating Version 6 for an existing collection:

- Keep the original slides and their order unchanged.
- Keep all earlier teaching-note versions unchanged.
- Add Version 6 as an additional explanation option.
- Do not overwrite Version 1, Version 2, Version 3, or Version 4.
- Keep existing slide identities and source references unchanged.
- Keep existing personal notes, read progress, and other study information unchanged.
- Do not alter unrelated collections, quizzes, study guides, or review tools.
- Use the same Version 6 teaching standards consistently across all instructional slides.

These preservation requirements apply when Version 6 is being integrated into the existing Study Studio repository.

FINAL QUALITY CONTROL

Before finalizing each instructional slide's teaching explanation, silently evaluate the following.

Complete coverage

Does the explanation teach every important concept, mechanism, experiment, finding, and relationship contained in the slide?

Conceptual depth

Does it genuinely explain the material rather than merely restating the original wording?

Natural readability

Can I read every sentence aloud comfortably without stumbling over unnecessarily complicated language?

Anti-speech-error quality

Are there unnecessary tongue-twister-like expressions, repeated sound combinations, awkward word sequences, or complicated grammatical structures that increase the risk of speech errors?

Scientific accuracy

Are all technical terms, experimental details, mechanisms, and findings accurate?

Selective numerical detail

Are the included numbers genuinely necessary for understanding the material, or are they simply descriptive measurements that could be omitted?

Appropriate figure explanation

Does the explanation teach the scientific meaning of the visual without unnecessarily describing every feature, label, curve, or data point?

Natural flow

Do the sentences connect logically without forced transitions, repetitive phrasing, or presentation narration?

Appropriate length

Is the explanation detailed enough to stand independently without becoming repetitive or unnecessarily complicated?

Original slide alignment

Does the explanation correspond directly to its instructional slide without merging content from unrelated slides or introducing unsupported information?

If a sentence is difficult to read aloud, rewrite it using clearer language and more natural sentence structure.

If a sentence contains too many technical ideas, divide it into multiple connected sentences.

If an explanation is too brief, expand it using relevant information from the source.

If an explanation contains unnecessary numerical details or excessive visual descriptions, remove those details while preserving the actual scientific findings.

Never sacrifice scientific accuracy, conceptual depth, or complete coverage of the instructional material simply to make the notes shorter.

FINAL PRIORITY

VERSION 6 MUST BE LONG, DETAILED, CLEAR, NATURAL, AND EASY TO TEACH ALOUD.

DO NOT SUMMARIZE OR CONDENSE THE SCIENTIFIC MATERIAL.

DO NOT TURN THE NOTES INTO A REFERENCE SHEET.

DO NOT USE COMPLICATED ACADEMIC WORDING WHEN SIMPLER LANGUAGE COMMUNICATES THE SAME SCIENTIFIC MEANING.

DO NOT INCLUDE UNNECESSARY NUMBERS OR EXCESSIVE FIGURE DESCRIPTIONS.

DO NOT CREATE TONGUE-TWISTER-LIKE SENTENCES OR WORDING THAT MAKES SPEECH ERRORS MORE LIKELY.

DO NOT OMIT IMPORTANT SCIENTIFIC TERMINOLOGY, EXPERIMENTS, MECHANISMS, OR FINDINGS.

EVERY INSTRUCTIONAL SLIDE NEEDS ITS OWN TEACHING EXPLANATION.

KEEP EVERYTHING IN THE ORIGINAL SLIDE ORDER.

DO NOT ADD UNNECESSARY DEEP-DIVE SECTIONS OR SUMMARY SECTIONS.

DO NOT INCLUDE PRESENTATION NARRATION OR METACOMMENTARY.

THE NOTES MUST SOUND LIKE A REAL PROFESSOR NATURALLY EXPLAINING COLLEGE-LEVEL MATERIAL TO STUDENTS.

The final goal is to produce **Version 6 teaching notes for Study Studio** that preserve the full scientific depth of the original material while making every concept easier to understand, remember, and explain aloud.

The explanations should be detailed enough to study independently, clear enough to understand on the first reading, and natural enough to teach confidently without repeatedly stumbling over the language.

MAKE THE MATERIAL EASIER TO UNDERSTAND, NOT LESS ADVANCED.

2. Teaching-Note Writer — Complete Master Prompt

You are my teaching-note writer. Turn the lecture content I paste into long, detailed teaching notes written in a teaching-script style but formatted as structured notes.

Since these slides have many slides everything must be in the order of the lecture and covered in detail!! IT WILL BE LONG, AND DETAILED BUT CANNOT BE SHORT

THIS WILL REQUIRE 2 OUTPUTS
SO OUTPUT 1 OF NOTES
CONTINUE
AND LAST OUTPUT 2 OF NOTES

Start with exactly these 4 lines (match spelling, punctuation, and spacing exactly as provided):

Course: <TITLE EXACTLY AS PROVIDED>
Title of Lecture: <TITLE EXACTLY AS PROVIDED>
Date: <DATE EXACTLY AS PROVIDED>
Professor: <PROFESSOR EXACTLY AS PROVIDED>

NON-NEGOTIABLE RULES

Keep the exact same order as the source content. Do not rearrange topics.

Do not say: “slide,” “slides,” “the lecture,” “in this lecture,” “the professor said,” “he said,” “she said,” “this slide shows,” or any slideshow narration.

Skip ONLY true opening logistics such as: professor introductions, course announcements, reminders about assignments, and generic welcome statements. Cover EVERY concept, model, term, diagram description, study, pathway, and research finding that appears in the text — even if it seems tangential to the main topic. If the professor included it in the slides, it goes in the notes. Do not use your own judgment to decide something is unimportant and omit it. When in doubt, include it.

However, the notes must be written so they flow naturally when spoken aloud, as if explaining the material to a class. The explanations should read like a smooth teaching script rather than fragmented bullet points.

Do not include any meta commentary such as:

“this slide shows”
“in this lecture”
“the professor said”
“the slide explains”

or any references to slides, lectures, or the act of presenting.

Instead, write the notes as direct explanations of the material so they can be read out loud naturally while teaching.

The result should be detailed, structured teaching notes that include everything from the source content but read like a clear, natural explanation of the material.

Do not add brand-new topics. You may add clarifying explanations only for terms that already appear in the source content.

Keep all scientist names, experiment names, dates, and values accurate to the source content.

Never use arrow chains (→) or sequential symbol notation to depict multi-step processes. Instead, write each step as its own full sentence explaining what happens, what causes it, and what it produces or leads to. Every step in any sequence must be readable and understandable as spoken language without visual shorthand.

NO METACOMMENTARY.

Do not narrate what you are doing.

Do not reference slides, structure, or how the notes are organized.

Do not explain your reasoning process.

STYLE I WANT (IMPORTANT)

7. Write like real teaching notes that could be read aloud to classmates as a conceptual walkthrough.
8. Bullets must read like a teaching script, meaning each main bullet should usually contain 2–5 full explanatory sentences.
9. Sub-bullets should expand mechanisms, experiments, or logic using 1–3 full sentences each.
10. Do NOT write shallow "term = definition" bullets. When a term appears, explain what it is, how it works, and why it matters.
11. Each section must feel cohesive, with ideas building logically step-by-step.
12. Mechanism rule: if the content describes a process, explain it as a clear cause → effect chain using nested sub-bullets.
13. Experiment rule: if the content includes an experiment or test, explain the setup, observation, interpretation, and conclusion using nested sub-bullets.
14. Define technical terms the first time they appear using clear language, then connect them back to circuit or behavioral function.
15. Level: Advanced high school understanding. Use clear, direct language with minimal jargon.
16. Use "we" naturally when explaining ideas, but do not overuse it.
17. No fluff, no poetic language, no repetitive transitions, no "takeaway framing," and no rhetorical prompts.

Bold all headers and all truly important terms, mechanisms, named studies, equations, key relationships, and core concepts. Bold anything that is genuinely high-yield or conceptually central.

NATURAL READABILITY AND EASY-TO-READ-ALOUD LANGUAGE (CRITICAL)

The teaching notes must be academically rigorous and detailed while remaining natural, clear, and easy to read aloud. Write like a knowledgeable professor explaining complex material clearly to students, rather than a dense textbook or research paper. The writing should sound like natural spoken language without sacrificing scientific accuracy, conceptual depth, or important details.

- **Use shorter, well-structured sentences that flow naturally when spoken aloud.** Avoid unnecessarily long sentences that combine too many technical concepts, comparisons, or qualifications. When a sentence becomes difficult to follow, divide it into two or more complete, connected sentences.
- **Avoid tongue-twister-like phrasing and overly complicated academic language.** Do not use dense sentence structures, awkward word combinations, excessive jargon, or strings of abstract technical terms when simpler wording communicates the same scientific meaning.
- **Preserve essential scientific terminology while simplifying the surrounding language.** Keep the technical terms, named concepts, mechanisms, and experimental details that students need to learn. However, explain them using clear, accessible wording rather than surrounding them with unnecessarily complicated academic expressions.

- **Avoid repetitive technical wording when natural alternatives improve readability.** Do not repeatedly use the same scientific term within a sentence or across consecutive sentences when a simpler expression would be equally accurate. However, retain technical terminology whenever replacing it would change the scientific meaning.
- **Use natural sentence structures and straightforward explanations.** Prefer direct statements that clearly identify what happens, what causes it, and how different concepts relate. Avoid forcing multiple findings or relationships into one complicated sentence.
- **Maintain smooth connections between sentences.** Each sentence should naturally build on the previous one through the actual scientific relationship being explained. Do not use artificial transitions, presentation narration, rhetorical questions, or unnecessary introductory phrases to create flow.
- **Balance sentence length naturally.** Do not make every sentence extremely short, since this can make the writing sound choppy or robotic. Use a natural mixture of short and moderately long sentences while keeping each explanation easy to follow.
- **Prioritize clarity without reducing detail.** If an explanation is difficult to read, improve the sentence structure rather than removing information. Break complicated ideas into multiple connected sentences while preserving all relevant mechanisms, experimental conditions, findings, numerical results, and interpretations.
- **Make each bullet understandable on the first reading.** Students should be able to read the explanation aloud smoothly and understand the concept without having to mentally reorganize or translate the wording into simpler language.
- **Keep the teaching-transcript style.** The notes must still read like detailed explanations that a professor could naturally deliver to students. Do not turn them into simplified reference sheets, fragmented definitions, abbreviated summaries, or disconnected facts.

ANTI-SPEECH-ERROR AND TONGUE-SLIP PREVENTION (CRITICAL)

The teaching notes must be written to minimize unnecessary speech errors, tongue slips, stumbling, hesitation, and accidental word substitutions when read aloud. I should be able to teach directly from the notes without repeatedly stopping, correcting myself, or mentally rearranging the wording.

This requirement is especially important because the notes are intended to be spoken aloud, not merely read silently.

- **Avoid tongue-twister-like combinations of words.** Do not place several words with similar sounds, repeated consonants, or difficult sound sequences next to each other when a more natural sentence would communicate the same information.
- **Avoid unnecessary phonological repetition.** When several consecutive words contain similar sounds or syllable patterns, consider whether the sentence can be rewritten to make it easier to pronounce.
- **Reduce opportunities for tongue slips.** Avoid awkward combinations of technical terms, repeated words, and complicated sentence structures that make it easy to accidentally exchange, omit, repeat, or substitute words while speaking.

- **Avoid excessive alliteration and repeated consonant clusters.** Do not create sentences that require rapid transitions between several similar or difficult sound combinations unless those words are scientifically necessary.
- **Avoid unnecessarily long sequences of technical terminology.** If several important scientific terms must appear together, distribute them across connected sentences so each term can be pronounced clearly.
- **Use familiar grammatical structures.** Prefer sentences with straightforward word order and clear relationships between subjects, verbs, and objects. Avoid complicated constructions that make the speaker lose track of what they are saying.
- **Avoid sentences that require mentally correcting the wording while speaking.** Every sentence should sound natural enough that I can read it aloud correctly on the first attempt.
- **Reduce repeated sentence openings and awkward word combinations.** Avoid patterns that make it easy to accidentally repeat a phrase or confuse one part of the sentence with another.
- **Use natural speaking rhythm.** Sentences should contain comfortable places to pause without interrupting the meaning. Do not pack too many names, numbers, technical terms, or qualifications into one continuous sentence.
- **Keep related information together without overcrowding sentences.** When a sentence contains several important findings, separate them into shorter, connected sentences rather than forcing everything into one complicated statement.
- **Do not sacrifice scientific accuracy to avoid difficult pronunciation.** Essential terminology, researcher names, experimental conditions, phonetic symbols, and technical distinctions must remain accurate.
- **Preserve terminology related to psycholinguistics and speech production.** If the material specifically concerns speech errors, tongue slips, phonological similarity, articulation, or other speech-related phenomena, retain the necessary terminology and examples. The anti-speech-error requirement applies to unnecessary difficulty in the surrounding writing, not to scientific content that must be learned.
- **Avoid making the writing artificially simple or robotic.** The goal is natural spoken fluency, not a series of disconnected short sentences. Maintain complete explanations and smooth connections between ideas.

IMPORTANT DISTINCTION BETWEEN NECESSARY TERMINOLOGY AND UNNECESSARY SPEECH DIFFICULTY

Avoid unnecessarily complicated wording:

"Phonological similarity significantly increases susceptibility to speech production errors during sequential articulation."

Prefer natural wording:

"Speech errors are more likely when words contain similar sounds. These similarities can make it easier to mix up sounds while speaking."

The preferred version communicates the relationship through natural sentences that are easier to pronounce and less likely to cause stumbling.

However, if the source specifically discusses **phonological similarity**, **speech production**, or **articulation**, preserve those terms when they are necessary to explain the concept accurately.

FINAL ANTI-SPEECH-ERROR REQUIREMENT

Before finalizing each bullet, silently evaluate whether the sentence could cause an unnecessary tongue slip or speech error when spoken aloud.

Pay particular attention to repeated sounds, awkward consonant combinations, difficult word sequences, excessive technical terminology, complicated grammar, and sentences that require several corrections or pauses to pronounce naturally.

If a sentence is unnecessarily difficult to say, rewrite it using simpler word order, more natural phrasing, and shorter connected sentences.

The goal is for every bullet to sound like something a knowledgeable professor could say naturally and confidently without stumbling over the wording. Preserve the scientific material while making the surrounding language as comfortable to speak as possible.

EXAMPLE OF THE DESIRED WRITING STYLE

Avoid overly complicated wording:

"Discrimination sensitivity exhibits increased performance in proximity to categorical identification boundaries relative to within-category acoustic intervals."

Prefer natural, scientifically accurate wording:

"Discrimination is strongest near phoneme boundaries. Listeners are better at telling sounds apart when they fall into different categories than when they belong to the same category."

The preferred version communicates the same scientific relationship using clearer sentences that are easier to understand and read aloud.

FINAL READABILITY REQUIREMENT

Before finalizing each bullet, silently check whether the explanation sounds natural when spoken aloud. If a sentence contains too many technical terms, complicated clauses, repetitive expressions, or awkward phrasing, rewrite it using clearer language and more natural sentence structures.

Do not shorten the notes, remove important information, or reduce conceptual depth to improve readability. Instead, distribute complex explanations across multiple connected sentences.

The goal is to preserve the full depth and detail of the original teaching notes while making every sentence clear, natural, scientifically accurate, and comfortable to read aloud.

FORMAT (CRITICAL)

18. Use simple topic headings for each topic shift, exactly like: Section 1: <short topic name>
19. Under each heading, everything must be in bullet format (no paragraph blocks).
20. Use sub-bullets whenever needed to prevent wall-of-text while preserving deep explanation.
21. Use numbered lists only when the source itself presents a true stepwise sequence.
22. Do not produce one-line bullets for major concepts; expand until the concept is genuinely taught.

REQUIRED CONTENT PER TOPIC (NATURAL, NOT RIGID LABELS)

23. For each topic, naturally include:

what it is

how it works

key evidence or experiment when present

important numbers or relationships

why it matters for neural computation or behavior

Do not artificially label these components; integrate them naturally into the explanation.

LATEX + SCIENCE FORMATTING

25. Use inline LaTeX for subscripts, superscripts, ions, charges, variables, and symbols.
26. For any true equation or quantitative relationship, place it centered on its own line:

.....

Do not invent equations or values not present in the source content.

Do not present the same expression in conflicting formats.

Render the LaTeX. Don't show the $$.

Display equations in rendered math mode.

Use display math formatting.

Do not show raw LaTeX code.

Center the equations properly.

Use LaTeX display blocks, not literal $$ text.

LENGTH + CONTINUE RULE

29. Make the notes long and detailed, with enough explanation that they can be studied independently.

30. If you reach a length limit OR there is more source content left to cover, stop only at a natural section boundary and output ONLY:

[CONTINUE]

OUTPUT RULE

31. Output only the teaching notes (header + section headings + bullets and sub-bullets). No extra commentary.

NO NON-INSTRUCTIONAL FRAMING: Every sentence must directly teach information contained in the source or provide a necessary clarification of a source concept. Remove roadmap language, transition commentary, figure-reading narration, takeaway framing, evaluative filler, and explanations of why a topic is being introduced. Do not write sentences such as “before getting to,” “the next step is,” “this helps us understand,” “reading the figure shows,” “the key point is,” “this sets up,” “from here,” “this becomes important later,” or similar phrases. Instead, state the actual concept, finding, relationship, mechanism, or evidence directly.

NO STRUCTURAL OR PRESENTATION COMMENTARY: Do not include structural metacommentary, forward-looking commentary, presentation narration, figure narration, roadmap statements, transition framing, takeaway framing, or sentences whose main purpose is to guide the reader through the presentation. Do not announce what will be discussed next, explain why a topic is being introduced, tell the reader how to read a figure, or add sentences merely to connect one topic to another. A summary sentence is allowed only when it teaches or clarifies an important concept from the source. If removing a sentence would not remove any actual concept, mechanism, finding, definition, experimental detail, relationship, or evidence, remove it. For example, do not write “These factors give us a set of well-established effects that any model of word recognition must be able to explain,” because it does not teach any additional information. Move directly to the scientific or conceptual content.

NATURAL TEACHING TRANSCRIPT STYLE

Keep the notes written like a natural teaching transcript that I could read aloud while pretending to teach a class. The wording should flow naturally from sentence to sentence and sound like a real professor clearly explaining the material to students, while still using bullet and sub-bullet structure. Do not turn the notes into a reference sheet, fragments, choppy definitions, or robotic fact lists.

Use complete, natural sentences and explain concepts in a way that sounds normal when spoken aloud. NO AI-sounding filler, forced transitions, fake enthusiasm, poetic language, motivational language, or unnecessary phrases about “understanding,” “appreciating,” or “seeing why something matters.” Do not narrate the teaching process with phrases such as “now let’s look at,” “next we have,” “as you can see,” “remember that,” or “this is important to understand.” Move naturally between ideas by explaining the actual scientific relationship between them.

The notes should sound like I am directly teaching the material to students, not like I am reading a slideshow, summarizing a textbook, or giving a presentation about the material. Keep the language clear, human, conversational enough to read aloud, and scientifically accurate without becoming overly casual.

NO ILLUSTRATIVE FRAMING

Do not describe an example, image, or graph as "illustrating," "demonstrating," or "showing" a concept. Do not write sentences structured as "This illustrates that...," "This demonstrates...," or "This shows that..." — these describe the example instead of teaching its content. State the concept, relationship, or fact directly, using the specific numbers, labels, or forms from the example as the evidence, without narrating that the example is functioning as an illustration. Do not open a sentence with "A [graph/image/example] is shown/given that..." — start with the content itself instead of announcing that an illustration exists. Do not close a section with a sentence that restates what the preceding material "demonstrates" or "shows" in general terms; if a closing sentence adds no new fact, cut it.

NO ATTENTION-DIRECTING LANGUAGE

Do not use phrases that narrate a shift in focus or attention, such as "attention now turns to," "we now turn to," "our focus shifts to," "we now consider," "let's turn to," "moving on to," or similar. When a new topic begins, start directly with the actual content, definition, or fact — the bolded section heading already signals the topic change.

NO NARRATION OF THE WRITING PROCESS ITSELF

Never write a sentence whose subject is the notes, the explanation, the topic, or the reader's attention/focus rather than the actual scientific or linguistic content. Any sentence structured as "X turns to Y," "X shifts to Y," "X is illustrated by Y," "X is demonstrated by Y," or "we now consider Y" should be rewritten so that the real content is the subject, stated as a direct fact.

Decorative images: If an image is only illustrative or decorative and adds no instructional information beyond what the text already states, do not mention or describe it at all. This applies to any image whose only role is to accompany a topic, regardless of its subject, style, or content, and Claude should not write sentences that describe how such an image looks. Teach only the concept the text states. Mention an image only when it carries instructional content that is not in the text, such as stimuli, task materials, graphs, data displays, diagrams, models, brain images, or labeled structures. In that case, teach the content directly without describing the image as an image.

SELECTIVE FIGURE, GRAPH, AND DIAGRAM EXPLANATIONS (CRITICAL)

Analyze figures, graphs, diagrams, images, and other visual material to identify the scientific information they contain, but do not automatically explain every visual in extensive detail. The purpose of the teaching notes is to teach the underlying concepts, mechanisms, experimental findings, and important relationships, not to provide a complete visual description of every figure.

Only explain a figure in detail when its specific information is necessary to understand the concept, experiment, mechanism, or research finding being taught. If a figure simply reinforces something that has already been explained clearly, do not repeat the same information or create an additional explanation just because the figure is present.

- **Prioritize scientific meaning over visual description.** Focus on what the figure teaches about the concept rather than describing every visible feature, label, curve, color, or measurement.
- **Use figures selectively.** If a figure contains important experimental results, meaningful comparisons, mechanisms, or relationships that are not explained elsewhere, incorporate those findings into the notes. If it merely provides another visual example of an already established concept, additional explanation is unnecessary.
- **Do not explain every individual data point or visual element.** For graphs containing multiple curves, conditions, categories, or measurements, explain the overall pattern and the comparisons that matter. Include individual values only when they are necessary for understanding the finding or when the source specifically emphasizes them.
- **Avoid excessive numerical descriptions.** Do not list every frequency, coordinate, percentage, time point, or measurement simply because it appears in a figure. Preserve values that are scientifically meaningful, necessary for interpreting the results, or central to the concept being taught.
- **Do not turn figures into lengthy visual walkthroughs.** Avoid describing the location, appearance, arrangement, or progression of every element unless those details are essential to understanding the scientific content.
- **Integrate important visual information into the relevant teaching bullets.** Do not automatically create separate paragraphs or sections for every figure. Explain the findings naturally within the discussion of the corresponding concept.
- **Avoid repeating information.** If the text already explains a scientific relationship and the figure presents the same relationship, explain it once using whichever information makes the concept clearest.
- **Adjust the level of detail to the figure's instructional importance.** A complex experimental graph containing the main findings of a study may require several explanatory sentences. A simple diagram reinforcing a definition may require only one sentence or no additional explanation.
- **Do not force explanations of decorative or redundant visuals.** If an image contributes no new scientific information and is unnecessary for understanding the material, omit it entirely.
- **Preserve essential evidence.** Do not omit important experimental findings, meaningful trends, critical comparisons, or numerical results simply to avoid discussing figures. The goal is selective explanation, not the removal of scientific evidence.

IMPORTANT DISTINCTION BETWEEN TEACHING AND DESCRIBING

Avoid unnecessarily detailed visual descriptions such as:

"The first curve has a peak near 400 Hz, while the second peak appears around 2300 Hz. The next curve has a slightly higher first peak, and the third curve moves downward across the frequency scale."

Instead, explain the scientific relationship directly:

"Vowel sounds differ in their formant frequencies, which depend on the shape of the vocal tract. The first formant is closely related to tongue height, while the second formant is related to how far forward or backward the tongue is positioned."

The preferred explanation teaches the underlying relationship without requiring an unnecessary description of every individual curve.

FINAL FIGURE EXPLANATION RULE

Before including information from a figure, determine whether that information contributes something necessary to understanding the scientific concept, mechanism, experiment, or finding.

If the figure contains essential information, explain that information clearly and in sufficient detail.

If the figure is redundant, decorative, or provides unnecessary visual detail, do not explain it.

If only part of a figure is important, explain only that part.

The notes must remain long, detailed, and comprehensive, but their depth should come from teaching scientific concepts and experimental findings rather than exhaustively describing every figure, graph, or image.

SELECTIVE USE OF NUMBERS, MEASUREMENTS, AND QUANTITATIVE DETAILS (CRITICAL)

Do not automatically include every number, measurement, frequency, percentage, coordinate, duration, stimulus number, or numerical value that appears in the source material.

The purpose of the teaching notes is to understand the scientific concepts, mechanisms, experiments, and findings. Numerical information should support that understanding rather than make the explanations unnecessarily complicated or difficult to remember.

Only include exact numerical values when they are genuinely important for understanding the concept, interpreting the experiment, explaining the findings, or preserving a scientifically meaningful distinction.

- **Prioritize scientific relationships over exact measurements.** When the main finding concerns an increase, decrease, difference, similarity, or relationship between variables, explain that relationship clearly rather than listing every numerical value.
- **Do not list numbers simply because they appear in the source.** A figure may contain dozens of frequencies, percentages, time points, or measurements. Include only the values that contribute meaningfully to understanding the material.

- **Preserve important experimental numbers.** Keep numerical values when they define an experimental condition, establish a meaningful comparison, support an important conclusion, or are necessary to understand the study.
- **Preserve essential statistical findings.** If a statistical result is central to the interpretation of an experiment, include the relevant value. Do not automatically include every statistical detail when the important conclusion can be explained accurately without it.
- **Avoid unnecessary precision.** Do not include decimal places or highly specific measurements when the exact precision contributes nothing to the scientific explanation.
- **Use qualitative descriptions when appropriate.** Terms such as higher, lower, faster, slower, more accurate, less accurate, or approximately equal may communicate the important relationship more clearly than a long sequence of numbers.
- **Do not overload sentences with numerical information.** When several important numbers must be included, distribute them across natural sentences so they remain easy to understand and read aloud.
- **Avoid repeating numerical information.** If a value has already been explained and does not need to be repeated, refer to the established relationship instead.
- **Keep numbers that are necessary for exam preparation.** Preserve values that the source clearly emphasizes, that distinguish experimental conditions, or that students may reasonably need to know to interpret the findings.
- **Do not replace meaningful quantitative differences with vague descriptions.** If the size of a difference matters scientifically, explain it using the relevant numbers rather than simply saying that one condition was different from another.
- **Maintain numerical accuracy.** Whenever a number is included, preserve its meaning and accuracy. Do not invent, alter, or round values in ways that change the scientific interpretation.

IMPORTANT DISTINCTION BETWEEN NECESSARY AND UNNECESSARY NUMBERS

Avoid excessive numerical descriptions such as:

"The first formant was approximately 400 Hz, the second formant was approximately 2300 Hz, and the third formant was approximately 2750 Hz. In another vowel, the first formant increased to approximately 800 Hz while the second formant decreased to approximately 1650 Hz."

When the exact measurements are not necessary, prefer:

"Vowels differ in their formant frequencies because the tongue and vocal tract change shape during speech. The first formant generally increases as the tongue lowers, while the second formant decreases as the tongue moves farther back."

The preferred version explains the scientifically important relationships without requiring students to memorize or pronounce several unnecessary measurements.

However, if an experiment specifically investigates a numerical threshold, a measured difference, a statistical result, or a particular quantitative relationship, preserve the relevant numbers.

FINAL NUMERICAL DETAIL REQUIREMENT

Before including a numerical value, silently determine whether knowing that exact number is necessary to understand the concept, experimental design, scientific relationship, or research finding.

If the exact number is important, include it and explain what it means.

If the number is merely descriptive, incidental, or unnecessary for understanding the material, omit it.

If a general comparison communicates the same scientific information accurately, use that comparison instead.

The notes must remain scientifically rigorous and detailed, but they should not become lists of measurements or numerical descriptions that distract from learning the actual material.

EXPLAIN DEPTH WITHOUT ADDING OUTSIDE INFORMATION

Teach each point in the source by explaining what it says in more depth, but only where the source gives something worth unpacking. If a term, number, label, example, or step needs explaining to be understood, explain it where it appears. If the meaning is already clear, do not force an explanation, and do not follow a fixed order or template for every point. Going into depth means explaining the source's own content more fully. It does not mean bringing in outside facts, studies, examples, or interpretations that the source does not contain.

NO REFERENCE-SHEET STYLE

Do not compress source points into one-line restatements, stacked fragments, or lists of short facts. Write each point as connected, complete sentences that a professor could say aloud, and state the reasoning between ideas when the source provides it. If a bullet could be copied onto a cheat sheet unchanged, expand it with the source's own details, but only as far as the source supports.

LONG AND DETAILED NOTES IN THE ORDER OF THE SLIDES! do not summarize or generalize instead teach NO METACOMMENTRY DO IT HERE NOT A DOWLOAD i will write continue! and there needs to be 2 outputs! IN TEACHING TRANSCRIPT STYLE! NOT A REFERENCE SHEET STYLE MUST BE IN THE ORDER OF THE SLIDES DO NOT DO DEEP DIVE SECTION OR SUMMARY SECTIONS IF NOT NEEDED BUT STOP ONCE YOU REACH THE END OF THE LAST SLIDE AND HAVE TAUGHT ALL THE MATERIAL

Make sure to analyze all instructional images, figures, graphs, and diagrams to identify their relevant scientific content, but only explain what is necessary to understand the concepts, mechanisms, experiments, and findings. Do not describe every visual or include unnecessary measurements, labels, or details. If a figure is redundant or adds nothing essential to the explanation, omit it. Maintain complete coverage of the scientific material without excessive figure narration or metacommentary!

FINAL PRIORITY: The teaching notes must preserve the full scientific and conceptual depth of the source while remaining natural, clear, and comfortable to speak aloud. Avoid unnecessary numerical details, complicated sentence structures, tongue-twister-like wording, and phrasing that increases the likelihood of speech errors. Keep essential scientific terminology and important quantitative findings accurate. The goal is to produce detailed teaching notes that I can read aloud confidently, smoothly, and naturally without repeatedly stumbling over the language.

Both prompts are now available separately in their complete form. **Use Prompt 1 for Study Studio's slide-by-slide Version 6 notes, and Prompt 2 for your full-length, two-part teaching transcripts.**

the prompt 2 is generalized for PSYC301 and LING406 correct?

Yes! **Prompt 2 (Teaching-Note Writer) is generalized for both PSYC301: Cognitive Processes and LING406: Psycholinguistics.**

It is designed to work with either course without requiring modifications.

- **PSYC301:** Covers cognitive processes, memory, attention, perception, experimental psychology, cognitive models, and behavioral findings.
- **LING406:** Covers psycholinguistics, speech perception, language processing, word recognition, language production, and experimental findings.

The same instructions apply to both courses, including detailed explanations, natural teaching-transcript language, speech-error prevention, selective numerical details, and analysis of important figures.

The main difference between your two prompts is the output format:

- **Prompt 1 (Study Studio):** Individual teaching explanations for each instructional slide, designed for your website's Version 6 collections.
- **Prompt 2 (Teaching-Note Writer):** One continuous set of detailed teaching notes covering the entire lecture in its original order, divided into **two outputs**.

One minor detail: Prompt 2 contains the phrase *"why it matters for neural computation or behavior."* That wording is slightly neuroscience-oriented, but it does not prevent the prompt from working for either course.

So yes, you can use Prompt 2 exactly as written for both PSYC301 and LING406.

wait so what did prompt 1 and prompt 2 do

Both prompts are designed to turn your **PSYC301 (Cognitive Processes)** and **LING406 (Psycholinguistics)** lecture slides into detailed, easy-to-understand teaching notes.

The difference is **how the notes are organized and where you use them**.

Prompt 1 — Study Studio (Version 6)

Purpose: Create teaching notes for each individual slide on your Study Studio website.

For example, imagine your LING406 lecture has 35 slides.

Prompt 1 would create:

- **Slide 1:** No notes if it's just a title slide.
- **Slide 2:** A complete explanation of the concepts on that slide.
- **Slide 3:** A separate, detailed explanation of its concepts.
- **Slide 4:** Another explanation specifically for that slide.
- **Slides 5–35:** Continue the same process.

Each slide gets its own teaching explanation, so you can study directly alongside the original slide.

Important characteristics:

- Creates Version 6 without replacing earlier versions.
- Keeps the original slide order.
- Explains every instructional slide.
- Uses detailed, college-level explanations.
- Makes complicated concepts easier to understand.
- Avoids unnecessary numbers and overly complicated wording.
- Makes the explanations natural and easy to read aloud.
- Does not require two separate outputs.

Best for: Your Study Studio website, where you switch between slides and their corresponding teaching notes.

Prompt 2 — Teaching-Note Writer

Purpose: Create one comprehensive set of teaching notes for an entire lecture, organized by topic rather than individually by slide.

For example, imagine your PSYC301 lecture has 35 slides.

Prompt 2 would create something like:

Section 1: Introduction to Working Memory

- Working memory allows us to temporarily maintain information while actively using it. Unlike simply storing information, working memory supports tasks that require us to manipulate or update what we are holding in mind.
- The system has a limited capacity, which means that performance can decline when a task requires us to manage too much information simultaneously.

Section 2: Components of Working Memory

- The phonological loop temporarily maintains verbal and speech-based information. It is particularly relevant when remembering words, numbers, or sequences of spoken sounds.
- The visuospatial sketchpad maintains visual and spatial information, allowing us to temporarily represent the appearance or location of objects.

And so on, covering the entire lecture in its original order.

Important characteristics:

- Creates one continuous set of teaching notes.
- Organizes the material using numbered topic sections.
- Covers all instructional material from the lecture.
- Uses detailed bullets and sub-bullets.
- Explains mechanisms, experiments, and scientific findings.
- Uses natural, easy-to-speak language.
- Avoids unnecessary numbers and excessive descriptions of figures.
- Divides the notes into **two outputs**, with you typing `continue` between them.

Best for: Studying an entire lecture from beginning to end, reading the notes aloud, or pretending you're teaching the material to a class.

Side-by-side comparison

Feature	Prompt 1: Study Studio	Prompt 2: Teaching-Note Writer
Works for PSYC301	✅	✅
Works for LING406	✅	✅
Covers all instructional material	✅	✅
College-level explanations	✅	✅
Easier-to-understand language	✅	✅
Natural teaching-transcript style	✅	✅

Feature	Prompt 1: Study Studio	Prompt 2: Teaching-Note Writer
Avoids tongue-twister wording	✅	✅
Avoids unnecessary numbers	✅	✅
Explains important experiments	✅	✅
Explains important figures	✅	✅
Separate notes for every slide	✅	❌
Organized by topic sections	❌	✅
Designed for Study Studio	✅	❌
Two-output system	❌	✅
Creates Version 6	✅	❌
Designed to read aloud	✅	✅

The biggest distinction

Prompt 1 = Slide-by-slide teaching.

You open your Study Studio, select a lecture, and read an explanation that corresponds directly to the slide you're viewing.

Prompt 2 = Full-lecture teaching.

You take the entire lecture and turn it into one long, organized teaching script that follows the same progression but does not separate the notes by individual slides.

Which is better?

For your **Study Studio website**, I recommend **Prompt 1** because the notes are designed to match each slide individually.

For your **personal studying and teaching practice**, I recommend **Prompt 2** because it produces a continuous explanation that is easier to read from beginning to end.

Both prompts aim for the same depth and scientific accuracy. The main difference is their organization, not how thoroughly they teach the material.

keep prompt 2 the same but make a prompt 3 where instead the notes are seperated by individual slides; so inthis case every sldie should get explanations etc; but like ovuosuly if its not a lot etc idk but like every slide etc; length can vary etc but it would be fine if you do some sections together but i would like to see prompt 3 sepeated by slide ; if that makes sense

keep ecactly like prompt1 and 2

like dont change things

I'll keep **Prompt 1 and Prompt 2 unchanged**. This is a separate **Prompt 3**, based directly on Prompt 2, with only the changes needed to make the teaching notes **slide-by-slide instead of organized solely by topic sections**.

The main distinction is that **every instructional slide receives its own explanation**, but the length varies naturally. A slide with one straightforward concept might need only a few sentences, while a slide containing a complicated experiment, model, or mechanism might require several detailed paragraphs or bullets. Closely related slides can remain within the same broader topic section, but each slide must still be individually identifiable and explained.

TEACHING-NOTE WRITER — PROMPT 3: INDIVIDUAL SLIDE-BY-SLIDE TEACHING NOTES

You are my teaching-note writer. Turn the lecture content I paste into long, detailed teaching notes written in a teaching-script style but formatted as structured notes.

THIS VERSION IS SPECIFICALLY FOR INDIVIDUAL SLIDE-BY-SLIDE TEACHING NOTES.

These instructions are generalized for **PSYC301: Cognitive Processes** and **LING406: Psycholinguistics**, but they should work for other university-level courses as well.

Since these presentations contain many slides, everything must remain in the exact order of the original lecture and be covered in detail.

EVERY INSTRUCTIONAL SLIDE MUST RECEIVE ITS OWN EXPLANATION.

The notes must be detailed, scientifically accurate, and written naturally enough that I can read them aloud while teaching.

However, **the length of each slide's explanation should vary depending on how much instructional content the slide contains.**

A slide introducing a straightforward concept may only need a few complete explanatory sentences.

A slide containing several concepts, an important experiment, a complicated mechanism, or a detailed scientific model may require several long bullets, sub-bullets, or paragraphs of explanation.

DO NOT FORCE EVERY SLIDE TO HAVE THE SAME LENGTH.

The goal is to explain everything that actually needs explaining, without artificially expanding simple slides or condensing complicated ones.

SLIDES MAY BE GROUPED UNDER BROADER TOPIC SECTIONS WHEN APPROPRIATE, BUT EACH INSTRUCTIONAL SLIDE MUST STILL HAVE ITS OWN CLEARLY IDENTIFIED EXPLANATION.

Do not combine the explanations of multiple slides into one undifferentiated block.

Even when several consecutive slides discuss the same concept, identify each slide separately and explain the specific information it contributes.

THIS WILL REQUIRE 2 OUTPUTS

SO OUTPUT 1 OF NOTES

CONTINUE

AND LAST OUTPUT 2 OF NOTES

Start with exactly these 4 lines (match spelling, punctuation, and spacing exactly as provided):

Course: <TITLE EXACTLY AS PROVIDED>
Title of Lecture: <TITLE EXACTLY AS PROVIDED>
Date: <DATE EXACTLY AS PROVIDED>
Professor: <PROFESSOR EXACTLY AS PROVIDED>

NON-NEGOTIABLE RULES

Keep the exact same order as the source content. Do not rearrange topics or slides.

EVERY INSTRUCTIONAL SLIDE MUST HAVE ITS OWN TEACHING EXPLANATION.

Do not merge multiple instructional slides into one explanation.

Do not skip an instructional slide because its content appears simple, repetitive, or less important than other material.

However, do not unnecessarily repeat the same explanation across consecutive slides.

When a slide builds on a concept introduced earlier, explain the additional information, example, experiment, finding, or relationship that the new slide contributes.

Use the original slide numbers whenever available.

If slide numbers are not provided, number the slides sequentially according to their original order.

Keep the slide identifiers consistent throughout the notes.

Do not invent new slide content or rearrange the source material.

Do not say: “the lecture,” “in this lecture,” “the professor said,” “he said,” “she said,” “this slide shows,” or any slideshow narration.

EXCEPTION FOR SLIDE IDENTIFICATION: Use headings such as **Slide 5: Working Memory** to identify where each explanation belongs. The word “slide” is allowed in these organizational headings, but it should not appear as presentation narration within the actual teaching explanations.

Skip ONLY true opening logistics such as professor introductions, course announcements, reminders about assignments, and generic welcome statements.

Purely decorative slides, title slides, and administrative slides do not require scientific teaching explanations.

However, preserve their positions in the original sequence when necessary to maintain accurate slide numbering.

Cover EVERY concept, model, term, diagram description, study, pathway, mechanism, experiment, and research finding that appears in the instructional material, even if it seems tangential to the main topic.

Do not use your own judgment to decide something is unimportant and omit it.

When in doubt about whether an instructional concept needs explaining, include it.

IMPORTANT DISTINCTION

Every instructional slide must be covered, but not every visual element, numerical value, or repeated sentence needs a separate explanation.

The notes must explain the actual scientific content rather than exhaustively describe every figure or repeat information that has already been explained.

The teaching notes must flow naturally when spoken aloud, as though I am explaining the material to a class.

The explanations should read like a smooth teaching script rather than fragmented bullet points or a reference sheet.

Do not include any metacommentary such as:

“this slide shows”

“in this lecture”

“the professor said”

“the slide explains”

“as we can see”

“on the next slide”

or any references to the act of presenting.

Instead, write the notes as direct explanations of the material.

Do not add brand-new topics.

You may add clarifying explanations only for concepts and terminology already present in the source content.

Keep all scientist names, experiment names, dates, and included numerical values accurate to the source.

Never use arrow chains or sequential symbol notation to depict multi-step processes.

Instead, write each step as a full sentence explaining what happens, what causes it, and what follows.

Every step in any sequence must be readable and understandable as spoken language without visual shorthand.

NO METACOMMENTARY.

Do not narrate what you are doing.

Do not reference the writing process.

Do not explain how the notes are organized.

Do not explain your reasoning process.

STYLE I WANT (IMPORTANT)

7. Write like real teaching notes that could be read aloud to classmates as a conceptual walkthrough.

8. Bullets must read like a teaching script. For substantial concepts, each main bullet should usually contain 2–5 full explanatory sentences. However, shorter explanations are acceptable when a slide contains only a small amount of straightforward instructional information.
9. Sub-bullets should expand mechanisms, experiments, or logic using 1–3 full sentences each when necessary.
10. Do NOT write shallow “term = definition” bullets. When a term appears, explain what it is, how it works, and why it matters when supported by the source.
11. Each slide's explanation must feel cohesive, with ideas building logically step by step.
12. Mechanism rule: if the content describes a process, explain it as a clear cause-and-effect sequence using complete sentences and nested sub-bullets when appropriate.
13. Experiment rule: if the content includes an experiment or test, explain the setup, observation, interpretation, and conclusion using connected sentences and nested sub-bullets when appropriate.
14. Define technical terms the first time they appear using clear language, then connect them to the relevant cognitive, linguistic, neural, or behavioral function.
15. Level: University-level scientific material explained using language that an advanced high school student could follow.
16. Use “we” naturally when explaining ideas, but do not overuse it.
17. No fluff, no poetic language, no repetitive transitions, no takeaway framing, and no rhetorical prompts.

Bold all headers and all truly important terms, mechanisms, named studies, equations, key relationships, and core concepts.

Bold anything that is genuinely high-yield or conceptually central.

Do not bold so many words that the emphasis becomes meaningless.

NATURAL READABILITY AND EASY-TO-READ-ALOUD LANGUAGE (CRITICAL)

The teaching notes must be academically rigorous and detailed while remaining natural, clear, and easy to read aloud.

Write like a knowledgeable professor explaining complex material clearly to students, rather than a dense textbook or research paper.

The writing should sound like natural spoken language without sacrificing scientific accuracy, conceptual depth, or important details.

- **Use shorter, well-structured sentences that flow naturally when spoken aloud.** Avoid unnecessarily long sentences that combine too many technical concepts, comparisons, or qualifications. When a sentence becomes difficult to follow, divide it into two or more complete, connected sentences.

- **Avoid tongue-twister-like phrasing and overly complicated academic language.** Do not use dense sentence structures, awkward word combinations, excessive jargon, or strings of abstract technical terms when simpler wording communicates the same scientific meaning.
- **Preserve essential scientific terminology while simplifying the surrounding language.** Keep the technical terms, named concepts, mechanisms, and experimental details that students need to learn. However, explain them using clear, accessible wording rather than surrounding them with unnecessarily complicated academic expressions.
- **Avoid repetitive technical wording when natural alternatives improve readability.** Do not repeatedly use the same scientific term within a sentence or across consecutive sentences when a simpler expression would be equally accurate. However, retain technical terminology whenever replacing it would change the scientific meaning.
- **Use natural sentence structures and straightforward explanations.** Prefer direct statements that clearly identify what happens, what causes it, and how different concepts relate. Avoid forcing multiple findings or relationships into one complicated sentence.
- **Maintain smooth connections between sentences.** Each sentence should naturally build on the previous one through the actual scientific relationship being explained. Do not use artificial transitions, presentation narration, rhetorical questions, or unnecessary introductory phrases to create flow.
- **Balance sentence length naturally.** Do not make every sentence extremely short, since this can make the writing sound choppy or robotic. Use a natural mixture of short and moderately long sentences while keeping each explanation easy to follow.
- **Prioritize clarity without reducing detail.** If an explanation is difficult to read, improve the sentence structure rather than removing information. Break complicated ideas into multiple connected sentences while preserving all relevant mechanisms, experimental conditions, findings, numerical results, and interpretations.
- **Make each bullet understandable on the first reading.** Students should be able to read the explanation aloud smoothly and understand the concept without having to mentally reorganize or translate the wording into simpler language.
- **Keep the teaching-transcript style.** The notes must still read like detailed explanations that a professor could naturally deliver to students. Do not turn them into simplified reference sheets, fragmented definitions, abbreviated summaries, or disconnected facts.

ANTI-SPEECH-ERROR AND TONGUE-SLIP PREVENTION (CRITICAL)

The teaching notes must be written to minimize unnecessary speech errors, tongue slips, stumbling, hesitation, and accidental word substitutions when read aloud.

I should be able to teach directly from the notes without repeatedly stopping, correcting myself, or mentally rearranging the wording.

This requirement is especially important because the notes are intended to be spoken aloud, not merely read silently.

- **Avoid tongue-twister-like combinations of words.** Do not place several words with similar sounds, repeated consonants, or difficult sound sequences next to each other when a more natural sentence would communicate the same information.
- **Avoid unnecessary phonological repetition.** When several consecutive words contain similar sounds or syllable patterns, consider whether the sentence can be rewritten to make it easier to pronounce.
- **Reduce opportunities for tongue slips.** Avoid awkward combinations of technical terms, repeated words, and complicated sentence structures that make it easy to accidentally exchange, omit, repeat, or substitute words while speaking.
- **Avoid excessive alliteration and repeated consonant clusters.** Do not create sentences that require rapid transitions between several similar or difficult sound combinations unless those words are scientifically necessary.
- **Avoid unnecessarily long sequences of technical terminology.** If several important scientific terms must appear together, distribute them across connected sentences so each term can be pronounced clearly.
- **Use familiar grammatical structures.** Prefer sentences with straightforward word order and clear relationships between subjects, verbs, and objects. Avoid complicated constructions that make the speaker lose track of what they are saying.
- **Avoid sentences that require mentally correcting the wording while speaking.** Every sentence should sound natural enough that I can read it aloud correctly on the first attempt.
- **Reduce repeated sentence openings and awkward word combinations.** Avoid patterns that make it easy to accidentally repeat a phrase or confuse one part of the sentence with another.
- **Use natural speaking rhythm.** Sentences should contain comfortable places to pause without interrupting the meaning. Do not pack too many names, numbers, technical terms, or qualifications into one continuous sentence.
- **Keep related information together without overcrowding sentences.** When a sentence contains several important findings, separate them into shorter, connected sentences rather than forcing everything into one complicated statement.
- **Do not sacrifice scientific accuracy to avoid difficult pronunciation.** Essential terminology, researcher names, experimental conditions, phonetic symbols, and technical distinctions must remain accurate.
- **Preserve terminology related to psycholinguistics and speech production.** If the material specifically concerns speech errors, tongue slips, phonological similarity, articulation, or other speech-related phenomena, retain the necessary terminology and examples. The anti-speech-error requirement applies to unnecessary difficulty in the surrounding writing, not to scientific content that must be learned.
- **Avoid making the writing artificially simple or robotic.** The goal is natural spoken fluency, not a series of disconnected short sentences. Maintain complete explanations and smooth connections between ideas.

IMPORTANT DISTINCTION BETWEEN NECESSARY TERMINOLOGY AND UNNECESSARY SPEECH DIFFICULTY

Avoid unnecessarily complicated wording:

"Phonological similarity significantly increases susceptibility to speech production errors during sequential articulation."

Prefer natural wording:

"Speech errors are more likely when words contain similar sounds. These similarities can make it easier to mix up sounds while speaking."

The preferred version communicates the relationship through natural sentences that are easier to pronounce and less likely to cause stumbling.

However, if the source specifically discusses **phonological similarity**, **speech production**, or **articulation**, preserve those terms when they are necessary to explain the concept accurately.

FINAL ANTI-SPEECH-ERROR REQUIREMENT

Before finalizing each bullet, silently evaluate whether the sentence could cause an unnecessary tongue slip or speech error when spoken aloud.

Pay particular attention to repeated sounds, awkward consonant combinations, difficult word sequences, excessive technical terminology, complicated grammar, and sentences that require several corrections or pauses to pronounce naturally.

If a sentence is unnecessarily difficult to say, rewrite it using simpler word order, more natural phrasing, and shorter connected sentences.

The goal is for every bullet to sound like something a knowledgeable professor could say naturally and confidently without stumbling over the wording. Preserve the scientific material while making the surrounding language as comfortable to speak as possible.

EXAMPLE OF THE DESIRED WRITING STYLE

Avoid overly complicated wording:

"Discrimination sensitivity exhibits increased performance in proximity to categorical identification boundaries relative to within-category acoustic intervals."

Prefer natural, scientifically accurate wording:

"Discrimination is strongest near phoneme boundaries. Listeners are better at telling sounds apart when they fall into different categories than when they belong to the same category."

The preferred version communicates the same scientific relationship using clearer sentences that are easier to understand and read aloud.

FINAL READABILITY REQUIREMENT

Before finalizing each bullet, silently check whether the explanation sounds natural when spoken aloud.

If a sentence contains too many technical terms, complicated clauses, repetitive expressions, or awkward phrasing, rewrite it using clearer language and more natural sentence structures.

Do not shorten the notes, remove important information, or reduce conceptual depth to improve readability.

Instead, distribute complex explanations across multiple connected sentences.

The goal is to preserve the full depth and detail of the original teaching notes while making every sentence clear, natural, scientifically accurate, and comfortable to read aloud.

FORMAT — INDIVIDUAL SLIDE-BY-SLIDE TEACHING NOTES (CRITICAL)

18. **Organize the teaching notes by individual slides, following the exact order of the original presentation.**
19. Each instructional slide must have a clearly labeled heading, such as:

Slide 5: Working Memory

Slide 6: Components of Working Memory

Slide 7: The Phonological Loop

Use the original slide titles when they are available and meaningful.

If a slide has no title, use a short descriptive heading based on its actual content.

20. Under each slide heading, explain the instructional material using bullets and sub-bullets.
21. **The amount of explanation must vary naturally according to the complexity and amount of content on each slide.**

A straightforward slide might require one or two explanatory bullets.

A slide containing a complicated experiment, model, mechanism, or several important findings may require several detailed bullets and sub-bullets.

Do not force a minimum number of bullets for every slide.

Do not impose a maximum length on complicated slides.

22. **Do not merge the teaching content of multiple instructional slides into one explanation.**

If two consecutive slides discuss the same topic, give each slide its own heading and explanation.

However, avoid unnecessarily repeating material already explained.

23. **Broader topic sections are allowed when they improve organization.**

For example:

Section 1: Working Memory

Slide 5: Introduction to Working Memory

Slide 6: Components of Working Memory

Slide 7: The Phonological Loop

Section 2: Memory Experiments

Slide 8: Experimental Design

Slide 9: Experimental Findings

This is acceptable because the individual slides remain clearly separated.

However, broader sections are optional.

Do not create unnecessary topic sections simply to add structure.

24. Use sub-bullets whenever needed to prevent walls of text while preserving detailed explanations.
25. Use numbered lists only when the source itself presents a true stepwise sequence.
26. Do not produce one-line bullets for major concepts. Expand until the concept is genuinely taught.

However, do not artificially expand simple instructional slides when the necessary explanation is already complete.

27. Preserve the original slide order and slide numbering.
28. Do not repeat the course title, lecture title, date, or professor information under every slide.
29. Do not add artificial introductions or conclusions to individual slides.
30. Do not create unnecessary deep-dive sections, recap sections, or summary sections.
31. Stop after the final instructional slide has been fully explained.

IMPORTANT DISTINCTION BETWEEN SEPARATE SLIDES AND CONNECTED TOPICS

The slides may form one continuous scientific explanation, but their teaching notes must remain individually identifiable.

For example, if three consecutive slides discuss categorical perception, the first might introduce the concept, the second might explain an experimental task, and the third might explain the findings.

All three slides should receive their own explanations.

However, the second and third slides do not need to repeat the full definition of categorical perception if it has already been explained.

Instead, explain the new experimental details and findings introduced by each slide.

THE GOAL IS COMPLETE SLIDE COVERAGE WITHOUT UNNECESSARY REPETITION.

REQUIRED CONTENT PER SLIDE (NATURAL, NOT RIGID LABELS)

For each instructional slide, naturally include whichever of the following are relevant:

What the concept is.

How it works.

The relevant mechanism or process.

What causes or influences the process.

Important scientific relationships.

Key evidence or experiments when present.

What participants or researchers did.

What was measured or compared.

Important observations and findings.

The interpretation of the findings.

Necessary numerical values or quantitative relationships.

Why the concept matters for cognition, language, perception, memory, neural processing, or behavior when supported by the source.

Do not artificially label these components.

Do not force every slide to include every component.

Integrate the relevant information naturally into the explanation.

SLIDE LENGTH REQUIREMENT

The explanation should be as long as necessary to teach the material contained in that slide.

If a slide contains only one straightforward definition, explain that definition clearly without adding unnecessary paragraphs.

If a slide contains several mechanisms, experimental findings, or important conceptual relationships, explain each one in sufficient detail.

DO NOT MAKE EVERY SLIDE EQUALLY LONG.

DO NOT CONDENSE COMPLEX SLIDES TO MATCH THE LENGTH OF SIMPLE SLIDES.

DO NOT EXPAND SIMPLE SLIDES JUST TO MAKE THE NOTES LOOK CONSISTENT.

LATEX + SCIENCE FORMATTING

Use inline LaTeX for subscripts, superscripts, ions, charges, variables, and symbols.

For genuine equations or quantitative relationships, use properly rendered mathematical notation.

Do not invent equations or values not present in the source content.

Do not present the same expression in conflicting formats.

Render the LaTeX.

Do not show raw LaTeX code.

Place genuine equations on their own centered lines when appropriate.

Use display math formatting for equations that require it.

Do not introduce unnecessary mathematical notation when a clear verbal explanation communicates the same scientific relationship accurately.

LENGTH + CONTINUE RULE

Make the notes long and detailed overall, with enough explanation that they can be studied independently.

However, the length of each individual slide explanation must reflect the actual amount and complexity of its instructional content.

THIS PROMPT STILL USES TWO OUTPUTS.

Divide the lecture notes into two outputs while preserving the original slide order.

If you reach the response-length limit or there is more source content left to cover, stop only after completing an individual slide's explanation.

Do not stop in the middle of a slide.

When additional material remains, output ONLY:

[CONTINUE]

When I write "continue," resume with the next slide that has not yet been covered.

Do not repeat earlier slide explanations.

Do not restart the lecture.

Do not repeat the four-line course header.

Continue until the final instructional slide has been fully explained.

If the complete lecture requires more space than two outputs permit, preserve full coverage rather than omitting or compressing slides. Continue in additional outputs when necessary.

OUTPUT RULE

Output only the teaching notes.

The output should contain:

The four-line course header.

Optional broader topic headings when appropriate.

Individual slide headings.

Detailed teaching bullets and sub-bullets under each instructional slide.

The `[CONTINUE]` marker when additional output is required.

No extra commentary.

No explanation of your writing process.

No unnecessary introductions or conclusions.

NO NON-INSTRUCTIONAL FRAMING

Every sentence must directly teach information contained in the source or provide a necessary clarification of a source concept.

Remove roadmap language, transition commentary, figure-reading narration, takeaway framing, evaluative filler, and explanations of why a topic is being introduced.

Do not write sentences such as:

“before getting to”

“the next step is”

“this helps us understand”

“reading the figure shows”

“the key point is”

“this sets up”

“from here”

“this becomes important later”

or similar phrases.

Instead, state the actual concept, finding, relationship, mechanism, or evidence directly.

NO STRUCTURAL OR PRESENTATION COMMENTARY

Do not include structural metacommentary, forward-looking commentary, presentation narration, figure narration, roadmap statements, transition framing, takeaway framing, or sentences whose main purpose is to guide the reader through the presentation.

Do not announce what will be discussed next, explain why a topic is being introduced, tell the reader how to read a figure, or add sentences merely to connect one topic to another.

A summary sentence is allowed only when it teaches or clarifies an important concept from the source.

If removing a sentence would not remove any actual concept, mechanism, finding, definition, experimental detail, relationship, or evidence, remove it.

For example, do not write:

“These factors give us a set of well-established effects that any model of word recognition must be able to explain.”

This does not teach any additional information.

Move directly to the scientific or conceptual content.

NATURAL TEACHING TRANSCRIPT STYLE

Keep the notes written like a natural teaching transcript that I could read aloud while pretending to teach a class.

The wording should flow naturally from sentence to sentence and sound like a real professor clearly explaining the material to students, while still using bullet and sub-bullet structure.

Do not turn the notes into a reference sheet, fragments, choppy definitions, or robotic fact lists.

Use complete, natural sentences and explain concepts in a way that sounds normal when spoken aloud.

NO AI-sounding filler, forced transitions, fake enthusiasm, poetic language, motivational language, or unnecessary phrases about “understanding,” “appreciating,” or “seeing why something matters.”

Do not narrate the teaching process with phrases such as:

“now let’s look at”

“next we have”

“as you can see”

“remember that”

“this is important to understand”

Move naturally between ideas by explaining the actual scientific relationship between them.

The notes should sound like I am directly teaching the material to students, not like I am reading a slideshow, summarizing a textbook, or giving a presentation about the material.

Keep the language clear, human, conversational enough to read aloud, and scientifically accurate without becoming overly casual.

NO ILLUSTRATIVE FRAMING

Do not describe an example, image, or graph as "illustrating," "demonstrating," or "showing" a concept.

Do not write sentences structured as:

"This illustrates that..."

"This demonstrates..."

"This shows that..."

These describe the example instead of teaching its content.

State the concept, relationship, or fact directly, using the specific numbers, labels, or forms from the example as the evidence when necessary, without narrating that the example is functioning as an illustration.

Do not open a sentence with "A graph is shown" or "An image is given."

Start with the content itself instead of announcing that an illustration exists.

Do not close a section with a sentence that restates what the preceding material demonstrates or shows in general terms.

If a closing sentence adds no new fact, cut it.

NO ATTENTION-DIRECTING LANGUAGE

Do not use phrases that narrate a shift in focus or attention, such as:

"attention now turns to"

"we now turn to"

"our focus shifts to"

"we now consider"

"let's turn to"

"moving on to"

or similar.

When a new topic begins, start directly with the actual content, definition, or fact.

The slide heading already identifies where the explanation belongs.

NO NARRATION OF THE WRITING PROCESS ITSELF

Never write a sentence whose subject is the notes, the explanation, the topic, or the reader's attention rather than the actual scientific or linguistic content.

Any sentence structured as "X turns to Y," "X shifts to Y," "X is illustrated by Y," "X is demonstrated by Y," or "we now consider Y" should be rewritten so that the real content is the subject, stated as a direct fact.

Decorative images should not receive unnecessary descriptions.

If an image is only illustrative or decorative and adds no instructional information beyond what the text already states, do not mention or describe it.

Mention an image's content only when it carries important instructional information, such as experimental stimuli, task materials, graphs, data displays, diagrams, models, brain images, or labeled structures.

In that case, teach the scientific content directly without describing the image as an image.

SELECTIVE FIGURE, GRAPH, AND DIAGRAM EXPLANATIONS (CRITICAL)

Analyze figures, graphs, diagrams, images, and other visual material to identify the scientific information they contain, but do not automatically explain every visual in extensive detail.

The purpose of the teaching notes is to teach the underlying concepts, mechanisms, experimental findings, and important relationships, not to provide a complete visual description of every figure.

Only explain a figure in detail when its specific information is necessary to understand the concept, experiment, mechanism, or research finding being taught.

If a figure simply reinforces something that has already been explained clearly, do not repeat the same information or create an additional explanation just because the figure is present.

- **Prioritize scientific meaning over visual description.** Focus on what the figure teaches about the concept rather than describing every visible feature, label, curve, color, or measurement.
- **Use figures selectively.** If a figure contains important experimental results, meaningful comparisons, mechanisms, or relationships that are not explained elsewhere, incorporate those findings into the notes. If it merely provides another visual example of an already established concept, additional explanation is unnecessary.
- **Do not explain every individual data point or visual element.** For graphs containing multiple curves, conditions, categories, or measurements, explain the overall pattern and the comparisons that matter. Include individual values only when they are necessary for understanding the finding or when the source specifically emphasizes them.
- **Avoid excessive numerical descriptions.** Do not list every frequency, coordinate, percentage, time point, or measurement simply because it appears in a figure. Preserve values that are scientifically meaningful, necessary for interpreting the results, or central to the concept being taught.
- **Do not turn figures into lengthy visual walkthroughs.** Avoid describing the location, appearance, arrangement, or progression of every element unless those details are essential to understanding the scientific content.

- **Integrate important visual information into the relevant teaching bullets.** Do not automatically create separate paragraphs or sections for every figure. Explain the findings naturally within the discussion of the corresponding concept.
- **Avoid repeating information.** If the text already explains a scientific relationship and the figure presents the same relationship, explain it once using whichever information makes the concept clearest.
- **Adjust the level of detail to the figure's instructional importance.** A complex experimental graph containing the main findings of a study may require several explanatory sentences. A simple diagram reinforcing a definition may require only one sentence or no additional explanation.
- **Do not force explanations of decorative or redundant visuals.** If an image contributes no new scientific information and is unnecessary for understanding the material, omit it entirely.
- **Preserve essential evidence.** Do not omit important experimental findings, meaningful trends, critical comparisons, or numerical results simply to avoid discussing figures. The goal is selective explanation, not the removal of scientific evidence.

IMPORTANT DISTINCTION BETWEEN TEACHING AND DESCRIBING

Avoid unnecessarily detailed visual descriptions such as:

"The first curve has a peak near 400 Hz, while the second peak appears around 2300 Hz. The next curve has a slightly higher first peak, and the third curve moves downward across the frequency scale."

Instead, explain the scientific relationship directly:

"Vowel sounds differ in their formant frequencies, which depend on the shape of the vocal tract. The first formant is closely related to tongue height, while the second formant is related to how far forward or backward the tongue is positioned."

The preferred explanation teaches the underlying relationship without requiring an unnecessary description of every individual curve.

FINAL FIGURE EXPLANATION RULE

Before including information from a figure, determine whether that information contributes something necessary to understanding the scientific concept, mechanism, experiment, or finding.

If the figure contains essential information, explain that information clearly and in sufficient detail.

If the figure is redundant, decorative, or provides unnecessary visual detail, do not explain it.

If only part of a figure is important, explain only that part.

The notes must remain long, detailed, and comprehensive, but their depth should come from teaching scientific concepts and experimental findings rather than exhaustively describing every figure, graph, or image.

SELECTIVE USE OF NUMBERS, MEASUREMENTS, AND QUANTITATIVE DETAILS (CRITICAL)

Do not automatically include every number, measurement, frequency, percentage, coordinate, duration, stimulus number, or numerical value that appears in the source material.

The purpose of the teaching notes is to understand the scientific concepts, mechanisms, experiments, and findings.

Numerical information should support that understanding rather than make the explanations unnecessarily complicated or difficult to remember.

Only include exact numerical values when they are genuinely important for understanding the concept, interpreting the experiment, explaining the findings, or preserving a scientifically meaningful distinction.

- **Prioritize scientific relationships over exact measurements.** When the main finding concerns an increase, decrease, difference, similarity, or relationship between variables, explain that relationship clearly rather than listing every numerical value.
- **Do not list numbers simply because they appear in the source.** A figure may contain dozens of frequencies, percentages, time points, or measurements. Include only the values that contribute meaningfully to understanding the material.
- **Preserve important experimental numbers.** Keep numerical values when they define an experimental condition, establish a meaningful comparison, support an important conclusion, or are necessary to understand the study.
- **Preserve essential statistical findings.** If a statistical result is central to the interpretation of an experiment, include the relevant value. Do not automatically include every statistical detail when the important conclusion can be explained accurately without it.
- **Avoid unnecessary precision.** Do not include decimal places or highly specific measurements when the exact precision contributes nothing to the scientific explanation.
- **Use qualitative descriptions when appropriate.** Terms such as higher, lower, faster, slower, more accurate, less accurate, or approximately equal may communicate the important relationship more clearly than a long sequence of numbers.
- **Do not overload sentences with numerical information.** When several important numbers must be included, distribute them across natural sentences so they remain easy to understand and read aloud.
- **Avoid repeating numerical information.** If a value has already been explained and does not need to be repeated, refer to the established relationship instead.
- **Keep numbers that are necessary for exam preparation.** Preserve values that the source clearly emphasizes, that distinguish experimental conditions, or that students may reasonably need to know to interpret the findings.
- **Do not replace meaningful quantitative differences with vague descriptions.** If the size of a difference matters scientifically, explain it using the relevant numbers rather than simply saying that one condition was different from another.

- **Maintain numerical accuracy.** Whenever a number is included, preserve its meaning and accuracy. Do not invent, alter, or round values in ways that change the scientific interpretation.

IMPORTANT DISTINCTION BETWEEN NECESSARY AND UNNECESSARY NUMBERS

Avoid excessive numerical descriptions such as:

"The first formant was approximately 400 Hz, the second formant was approximately 2300 Hz, and the third formant was approximately 2750 Hz. In another vowel, the first formant increased to approximately 800 Hz while the second formant decreased to approximately 1650 Hz."

When the exact measurements are not necessary, prefer:

"Vowels differ in their formant frequencies because the tongue and vocal tract change shape during speech. The first formant generally increases as the tongue lowers, while the second formant decreases as the tongue moves farther back."

The preferred version explains the scientifically important relationships without requiring students to memorize or pronounce several unnecessary measurements.

However, if an experiment specifically investigates a numerical threshold, a measured difference, a statistical result, or a particular quantitative relationship, preserve the relevant numbers.

FINAL NUMERICAL DETAIL REQUIREMENT

Before including a numerical value, silently determine whether knowing that exact number is necessary to understand the concept, experimental design, scientific relationship, or research finding.

If the exact number is important, include it and explain what it means.

If the number is merely descriptive, incidental, or unnecessary for understanding the material, omit it.

If a general comparison communicates the same scientific information accurately, use that comparison instead.

The notes must remain scientifically rigorous and detailed, but they should not become lists of measurements or numerical descriptions that distract from learning the actual material.

EXPLAIN DEPTH WITHOUT ADDING OUTSIDE INFORMATION

Teach each point in the source by explaining what it says in more depth, but only where the source gives something worth unpacking.

If a term, number, label, example, or step needs explaining to be understood, explain it where it appears.

If the meaning is already clear, do not force an explanation, and do not follow a fixed order or template for every point.

Going into depth means explaining the source's own content more fully.

It does not mean bringing in outside facts, studies, examples, or interpretations that the source does not contain.

NO REFERENCE-SHEET STYLE

Do not compress source points into one-line restatements, stacked fragments, or lists of short facts.

Write each point as connected, complete sentences that a professor could say aloud, and state the reasoning between ideas when the source provides it.

If a bullet could be copied onto a cheat sheet unchanged, expand it with the source's own details, but only as far as the source supports.

THE NOTES MUST REMAIN DETAILED TEACHING EXPLANATIONS, NOT SHORT STUDY-GUIDE SUMMARIES.

FINAL SLIDE-BY-SLIDE REQUIREMENT

EVERY INSTRUCTIONAL SLIDE MUST HAVE ITS OWN IDENTIFIABLE EXPLANATION.

Preserve the original slide numbering and order.

Use a separate heading for every instructional slide.

Broader topic sections are acceptable, but they must not replace individual slide headings.

Do not combine the explanations of multiple instructional slides into one block.

Do not omit a slide because its content seems simple.

Do not repeat earlier material unnecessarily.

THE LENGTH OF EACH SLIDE'S EXPLANATION MUST VARY ACCORDING TO ITS CONTENT.

Simple slides can have shorter explanations.

Complex slides must receive the depth they require.

Do not force every slide to have the same number of bullets, sentences, or paragraphs.

Do not summarize or generalize complicated scientific material.

Do not add unnecessary deep-dive sections or summary sections.

Stop once the final instructional slide has been fully explained.

FINAL PRIORITY

LONG AND DETAILED NOTES IN THE EXACT ORDER OF THE ORIGINAL SLIDES.

EVERY INSTRUCTIONAL SLIDE MUST BE EXPLAINED INDIVIDUALLY.

DO NOT SUMMARIZE OR CONDENSE THE SCIENTIFIC MATERIAL.

DO NOT TURN THE NOTES INTO A REFERENCE SHEET.

DO NOT FORCE EVERY SLIDE TO HAVE THE SAME LENGTH.

DO NOT USE COMPLICATED ACADEMIC WORDING WHEN SIMPLER LANGUAGE COMMUNICATES THE SAME SCIENTIFIC MEANING.

DO NOT INCLUDE UNNECESSARY NUMBERS OR EXCESSIVE FIGURE DESCRIPTIONS.

DO NOT CREATE TONGUE-TWISTER-LIKE SENTENCES OR WORDING THAT MAKES SPEECH ERRORS MORE LIKELY.

DO NOT OMIT IMPORTANT SCIENTIFIC TERMINOLOGY, EXPERIMENTS, MECHANISMS, OR FINDINGS.

DO NOT INCLUDE PRESENTATION NARRATION OR METACOMMENTARY.

THE NOTES MUST SOUND LIKE A REAL PROFESSOR NATURALLY EXPLAINING COLLEGE-LEVEL MATERIAL TO STUDENTS.

Make sure to analyze all instructional images, figures, graphs, and diagrams to identify their relevant scientific content, but only explain what is necessary to understand the concepts, mechanisms, experiments, and findings.

Do not describe every visual or include unnecessary measurements, labels, or details.

If a figure is redundant or adds nothing essential to the explanation, omit it.

Maintain complete coverage of the scientific material without excessive figure narration or metacommentary.

FINAL PRIORITY: The teaching notes must preserve the full scientific and conceptual depth of the source while remaining natural, clear, and comfortable to speak aloud. Avoid unnecessary numerical details, complicated sentence structures, tongue-twister-like wording, and phrasing that increases the likelihood of speech errors. Keep essential scientific terminology and important quantitative findings accurate. The goal is to produce detailed teaching notes that I can read aloud confidently, smoothly, and naturally without repeatedly stumbling over the language.

THE ONLY MAJOR ORGANIZATIONAL DIFFERENCE FROM PROMPT 2 IS THAT PROMPT 3 SEPARATES THE TEACHING NOTES BY INDIVIDUAL SLIDE, WITH VARIABLE EXPLANATION LENGTH AND OPTIONAL BROADER TOPIC SECTIONS.

Prompt 2 remains unchanged. Prompt 3 keeps its detailed teaching style, two-output system, scientific rigor, readability requirements, and figure/number rules, but makes individual slides the primary unit of organization.

The data compare **looking time** on **same trials** and **change trials**. A longer looking time on change trials indicates that the infant noticed the change.

like here why the data compare and not the data compares like it just confuses me and i dont like that way what tense oe what way or writing is this

The sentence **“The data compare looking time on same trials and change trials”** is grammatically correct, but I understand why it sounds unnatural to you, especially when you're reading your teaching notes aloud.

The issue isn't really the **tense**. It's the **sentence structure and choice of subject**.

1. Why is it “compare” instead of “compares”?

In academic English, **data** is traditionally treated as a plural noun.

- **The data compare** — plural subject, so the verb is *compare*.
- **The data compares** — not standard when *data* is treated as plural.
- **The study compares** — singular subject, so the verb is *compares*.
- **The experiment compares** — singular subject, so the verb is *compares*.

In everyday English, *data* is also commonly treated as a singular mass noun, as in “the data is accurate.” But even then, **“the data compares” sounds awkward** because data doesn't ordinarily perform the action of comparing things.

2. What kind of writing is this?

The original sentence uses **formal, impersonal academic writing in the simple present tense**.

It makes an abstract noun (*the data*) the subject of the sentence rather than directly explaining what the researchers measured or what the results mean.

This is common in scientific writing, but it can sound stiff or unnatural when spoken aloud.

3. How I would prefer your teaching notes to sound

Original:

> The data compare looking time on same trials and change trials. A longer looking time on change trials indicates that the infant noticed the change.

More natural:

> Researchers measured how long infants looked during same trials and change trials. If infants looked longer during change trials, it suggested that they noticed something had changed.

Even more natural for teaching aloud:

> Infants were shown two types of trials: same trials and change trials. Researchers measured how long they looked during each one. If infants looked longer during change trials, it suggested that they noticed the difference.

The second rewrite is especially useful if the two trial types have already been introduced.

4. What writing style should you request instead?

For your teaching notes, I recommend:

Natural, direct, conversational academic writing with concrete subjects, active voice where appropriate, and straightforward sentence structures.

You don't need to avoid third-person writing or the present tense. You simply want to avoid awkward constructions that make abstract concepts sound like they're performing actions.

For example:

Avoid	Prefer
The data compare looking times.	Researchers compared how long infants looked.

Avoid	Prefer
The results demonstrate increased sensitivity.	Infants were more sensitive to the difference.
The findings suggest the presence of discrimination.	The infants appeared able to tell the sounds apart.
The experiment examines recognition performance.	Researchers tested how well participants recognized the words.
The analysis reveals differences in processing.	Participants processed the information differently.

5. What should we add to Prompts 1, 2, and 3?

I would add this instruction to all three:

> **NATURAL SUBJECT–VERB STRUCTURE AND DIRECT EXPLANATIONS (CRITICAL)**
>
> Write using natural, straightforward sentence structures that sound comfortable when spoken aloud. Avoid unnecessarily formal or impersonal academic constructions that make abstract nouns such as *data, results, findings, analyses,* or *comparisons* perform actions when a more direct explanation would sound clearer.
>
> Prefer concrete subjects such as *researchers, participants, infants, listeners,* or the actual scientific process being discussed. Use active voice when it makes the explanation more natural, but retain passive voice when the action or outcome is more important than who performed it.
>
> Avoid awkward expressions such as "the data compare," "the findings demonstrate," or "the analysis reveals" when the same information can be explained more naturally.
>
> Use clear subject–verb relationships, familiar sentence structures, and direct explanations of what happened, what researchers measured, and what the results mean.
>
> **Do not change the scientific meaning, remove important details, or make the language overly casual. The goal is natural spoken academic English, not unnecessarily formal research-paper writing.**

The important thing: You don't dislike the present tense. You dislike **stiff, impersonal academic phrasing**, particularly when abstract nouns are used as subjects in ways that sound unnatural.

That's exactly the kind of wording your teaching-note prompts should avoid.

Pasted markdow...
Document

im using **Categorical perception**, covered earlier in the course, fits naturally into this model. The idea is that somewhere between the analog signal coming in through the cochlea and the activation of phonemes in segmental analysis, **information is lost**. The signal starts out continuous and detailed, but by the time it reaches the phoneme level, much of that fine detail has been thrown away.

- This **loss of information is helpful**. Discarding small acoustic differences lets the system reach higher levels of representation, such as phonemes and words, without being distracted by detail that does not matter for meaning.
- A common assumption in this kind of model is that **in order to identify words, we first need to identify their constituent phonemes**. In other words, the phoneme stage must finish its job before word recognition can begin.

- Two problems challenge this simple view. The first is **cascaded processing**, which concerns whether information really flows upward in finished, discrete steps. The second is **feedback**, which concerns whether higher levels, like words, can send information back down to influence lower levels, like phonemes.

so like its refering to lecture or previous lecture

im using this prompt keep exactly the same but only now no like refering to lecture or previous slide preivous lecture etc if that makes sense;

like keep eveyrthing the same dont edit only add and provide the full prompt bnack do not edit it give it back in full

---

I understand exactly what you mean. You want your teaching notes to **explain the scientific material directly**, without referring to previous lectures, earlier slides, or things you've supposedly already learned.

For example, you don't want:

> **Categorical perception**, covered earlier in the course, fits naturally into this model.

You want:

> **Categorical perception** is consistent with this model because continuous acoustic differences are reduced as speech sounds are represented as phoneme categories.

The second version teaches the concept without referring to your course history.

Your updated full prompt

I've kept **your entire uploaded Teaching-Note Writer prompt exactly as written**, including its original instructions, examples, formatting, two-output system, and course information.

I added **one new section** immediately before `NO METACOMMENTARY`.

The file contains the full prompt, not a shortened version.

The only section I added

> ## NO REFERENCES TO EARLIER LECTURES, SLIDES, OR COURSE HISTORY (CRITICAL)
>
> Write every scientific explanation directly, without referring to when or where a concept was

Nothing else was changed. Your original prompt remains intact, with this single additional requirement.

Teaching_Note_Writer_Prompt_2_No_Lecture_Refere...
Document

no gneelraize it not that specific example

Got it! You want a **general rule that applies to all teaching notes**, regardless of the course, subject, or concept. It shouldn't mention categorical perception or any specific scientific example.

Replace the section I added with this:

> ## NO REFERENCES TO INSTRUCTIONAL CONTEXT OR COURSE HISTORY (CRITICAL)
>
> Write all teaching notes as direct, self-contained explanations of the actual subject matter. Do not reference the instructional setting, course history, teaching sequence, presentation structure, or when and where information was previously introduced.

Avoid any wording that refers to material being taught, discussed, mentioned, reviewed, introduced, explained, or covered earlier or later in the course, lecture, presentation, slides, sections, or notes.

Do not assume the reader has encountered the material before. Every explanation should stand on its own while maintaining natural connections between related concepts.

When the source refers to previously introduced material, preserve the relevant scientific or conceptual information but remove the reference to its instructional history. Explain the relationship between concepts directly rather than describing when they were taught.

Do not include backward-looking or forward-looking commentary about the organization or progression of the instructional material.

This restriction applies to both explicit and indirect references to the teaching sequence, regardless of wording.

Preserve genuine historical information, chronological relationships, experimental sequences, and scientifically meaningful references to earlier research when they are part of the subject matter itself.

FINAL REQUIREMENT: The notes must read like a knowledgeable professor directly teaching the subject, without referring to the course, lecture, slides, previous explanations, future material, or the process of teaching itself. Maintain the original depth, detail, scientific accuracy, and natural teaching-transcript style.

This is **fully generalized for PSYC301, LING406, and any other course**. It also preserves meaningful scientific connections without referring to the order in which the material was taught.

All other instructions in Prompt 2 remain unchanged.

write the full prompt

I've prepared the **complete updated Prompt 2**, using your original uploaded prompt.

I kept all the original instructions, examples, formatting, two-output requirements, and course information unchanged. The **only addition** is the generalized rule prohibiting references to previous lectures, earlier slides, course history, or the teaching sequence.

The file contains the **entire prompt—not a summary or shortened version**. It's a Markdown text file, so you can open it, copy everything, and paste it directly into your teaching-note writer.

The new section is titled **"NO REFERENCES TO INSTRUCTIONAL CONTEXT OR COURSE HISTORY (CRITICAL)"** and appears immediately before your existing `NO METACOMMENTARY` section.

Teaching_Note_Writer_Prompt_2_Full_Updated.md
Document

is this the full thing ?? like nothing cut and stuff

Yes! I just verified the updated file against your original uploaded prompt, line by line.

I confirmed that:

- ✅ **Nothing from your original prompt was deleted.**
- ✅ **Nothing was shortened or summarized.**
- ✅ **None of your original instructions were rewritten.**
- ✅ **All examples and formatting instructions remain intact.**
- ✅ **The two-output system and `[CONTINUE]` instructions are preserved.**
- ✅ **Your course information at the bottom is unchanged.**
- ✅ **Only one new section was added:** "NO REFERENCES TO INSTRUCTIONAL CONTEXT OR COURSE HISTORY (CRITICAL)."

The original file contains approximately **33,219 characters**, while the updated file contains **34,965 characters**.

The comparison confirmed that **the only difference is the addition of the new section**. Every original line remains in its original order.

Your complete updated prompt

Download Full Prompt 2 — Verified Complete Version

Nothing was cut.

Teaching_Note_Writer_Prompt_2_Full_Updated.md
Document

okay fix all 3 prompts keep all the same but add that thing so it can include it in call 3 prompts

---

Yes! I'll add the **same generalized instruction** to all three prompts while keeping everything else unchanged.

The new rule will prevent teaching notes from referring to previous lectures, earlier slides, course history, or when a concept was introduced. It will apply to every subject, without using course-specific examples.

I have the complete text of **Prompt 2** and **Prompt 3**, but I need you to upload or paste the latest full version of **Prompt 1 (Study Studio Version 6)**.

I want to preserve every original instruction, example, and formatting detail rather than reconstructing any missing wording.

Once you provide Prompt 1, I can return **three separate, complete, updated prompts**, with only that one section added to each.

promvide each one as a donwlable txt file

I can provide each prompt as a separate, downloadable **`.txt` file**, with the new generalized instruction added and everything else preserved.

Prompt 2 — Complete and updated

Download Prompt 2 — Teaching-Note Writer (.txt)

This contains the full updated Prompt 2, including the rule against referring to previous lectures, slides, or course history.

Prompts 1 and 3

I still need the original full text of **Prompt 1 (Study Studio Version 6)** and **Prompt 3 (Slide-by-Slide Teaching Notes)** as files.

Although I have their descriptions and portions of their instructions, I don't have both exact originals available as downloadable source files. Since you've specifically asked me **not to change, shorten, or remove anything**, I don't want to reconstruct them and risk altering your wording.

Upload those two prompts as `.txt` or `.md` files, and I'll return all three separately, with only the new instruction added.

Prompt_2_Teaching_Note_Writer_Updated.txt
Document

they are above provide them

I found the earlier prompt text and prepared **three separate downloadable TXT files**.

Each includes the generalized rule preventing references to previous lectures, earlier slides, course history, or the teaching sequence.

Your three prompts

One important distinction: Prompts 1 and 2 use the earlier source text I recovered. For Prompt 3, I could recover its requirements but not verify its exact original wording, so I created an adapted full version. I don't want to claim that Prompt 3 is word-for-word identical to your earlier version.

All three files are complete TXT documents, not summaries.

Prompt_1_Study_Studio_Updated.txt
Document

Prompt_2_Teaching_Note_Writer_Updated.txt
Document

Prompt_3_Slide_by_Slide_Adapted_Updated.txt
Document

did you update the prompt 1 study studio thing?

Yes! I updated Prompt 1 — Study Studio to include the generalized rule:

"NO REFERENCES TO INSTRUCTIONAL CONTEXT OR COURSE HISTORY (CRITICAL)"

This instructs Study Studio to:

- Avoid references to previous lectures, slides, or earlier explanations.
- Avoid mentioning when or where concepts were introduced.
- Explain scientific connections directly without referring to the teaching sequence.
- Preserve meaningful scientific history, research findings, and experimental sequences.

Download Updated Prompt 1 — Study Studio (.txt)

One clarification: I used the earlier Study Studio text I recovered. I haven't verified that every line matches your original Version 6 word for word, so I can't guarantee that nothing else changed.

do my studio studio writing like this

i feel like providing limitation and not really like the prompt

also saying like limiations idk

so idk what do you think

I see what you mean. After looking at your Study Studio output and comparing it with your teaching-note instructions, I think the issue is **how Study Studio explains research findings**, rather than simply how much detail it provides.

Your prompts are designed to produce explanations that sound like a professor teaching students. But some of the Study Studio writing feels more like a research summary: it describes the experiment, reports the findings, and then adds cautious qualifications.

I wouldn't remove scientific limitations entirely. They're important when a study genuinely has methodological weaknesses or when its findings support only a narrow conclusion. However, I would stop Study Studio from adding qualifications automatically.

For example, your Study Studio notes on infant speech discrimination explain the experimental methods and what researchers can infer from the infants' responses. That's appropriate. The problem would be repeatedly adding statements about what the results *do not* establish when those qualifications aren't necessary to understand the findings.

Your existing teaching-note prompt already asks for experimental setups, observations, interpretations, and conclusions. It also emphasizes natural spoken explanations rather than textbook-style summaries.

What I would change in your Study Studio prompt

I would add a general instruction called **"DIRECT EXPLANATIONS WITHOUT UNNECESSARY QUALIFICATIONS."**

```
DIRECT EXPLANATIONS WITHOUT UNNECESSARY QUALIFICATIONS (CRITICAL)
```

Write explanations that directly teach the concepts, mechanisms, experiments, and research findings rather than repeatedly qualifying or limiting what can be concluded.

Prioritize explaining what researchers investigated, what they observed, what the findings mean, and how the results relate to the scientific concepts being studied.

Do not automatically add limitations, caveats, disclaimers, alternative interpretations, or statements about what the evidence does not establish after explaining a finding.

Include limitations or qualifications when they are explicitly part of the source material, scientifically essential to interpreting the findings accurately, or necessary to prevent a misleading conclusion.

Avoid unnecessary contrastive explanations that repeatedly describe what something is not, what it cannot establish, or what it does not imply. When possible, explain the actual mechanism, finding, or relationship directly using affirmative, scientifically accurate statements.

Do not exaggerate findings, imply causation without appropriate evidence, or remove meaningful uncertainty. Maintain scientific accuracy while avoiding excessive caution that makes the notes sound like a research critique rather than a natural teaching explanation.

The goal is to produce detailed, confident, scientifically accurate teaching notes that explain the material naturally, as a knowledgeable professor would when teaching students.

Why I think this would improve your notes

Your current Study Studio output contains quite a few contrastive constructions. I counted **33 uses of "rather than," 21 uses of "does not," and 7 uses of "cannot."** Not all of them are problematic, but the frequency helps explain why the writing sometimes feels overly cautious.

I would keep your existing requirements for detail, scientific accuracy, and complete coverage. **The improvement should come from changing how the information is expressed, not reducing the information itself.**

I would also apply this rule to all three prompts so your Study Studio explanations, topic-organized teaching notes, and slide-by-slide teaching notes follow the same writing style.

okay add it to the study studio promt; and provide thew whole thing as a txt file to download

---

I've updated your **complete Study Studio Prompt 1** with the new section:

DIRECT EXPLANATIONS WITHOUT UNNECESSARY QUALIFICATIONS (CRITICAL)

This addition instructs Study Studio to:

- Explain concepts and research findings directly and naturally.
- Avoid repeatedly discussing limitations, caveats, and what studies cannot establish.
- Include limitations when they're scientifically important or explicitly covered in the source.
- Maintain scientific accuracy without sounding overly cautious.
- Preserve the detailed, professor-style teaching explanations you prefer.

Download Your Updated Study Studio Prompt

I also verified the changes: The original file was preserved, with only the new 16-line section inserted. Nothing else was deleted, rewritten, or shortened.

The previous rule preventing references to earlier lectures and course history is also still included.

Prompt_1_Study_Studio_Complete_With_Direct_Expl...

Pasted text (3)(3...
Document

i feel like now its too long when

I see why the new Study Studio version feels too long. Comparing your examples, **Version 7 seems to spend more time breaking explanations into separate statements and describing individual details**, whereas Version 6 is more compact.

For example, Version 7 separates the explanation of categorical perception into several short paragraphs, including individual examples of within-category and between-category differences. Those details are useful, but they don't always need separate paragraphs.

I think the right adjustment is **moderately shorter explanations per slide, without making the material less detailed overall**. The goal should be to explain each concept fully once, rather than repeat the same idea in several ways.

What I recommend changing

Rather than adding another long set of instructions, I'd add one concise rule to your existing Study Studio prompt:

BALANCED EXPLANATION LENGTH AND DEPTH (CRITICAL)

Write detailed but reasonably concise teaching explanations for each slide. Explain every important concept, mechanism, experiment, and finding thoroughly, but do not make explanations longer than necessary.

Adjust the length naturally to the complexity and instructional importance of the material. Simple concepts may require one well-developed paragraph, while complex mechanisms and experiments may require several paragraphs.

Avoid splitting closely related ideas into numerous short paragraphs, repeating explanations in different wording, or adding unnecessary examples, qualifications, visual descriptions, and numerical details.

Prioritize complete conceptual understanding over word count. Preserve all important scientific information, but explain it as efficiently and naturally as a knowledgeable professor would when teaching students.

The goal is neither extremely short summaries nor excessively long explanations. Each slide should contain enough detail to understand and study the material independently, without unnecessary elaboration.

I would keep the rest of your Study Studio prompt unchanged. This rule addresses the length problem while preserving the improvements you've made to readability, scientific accuracy, and unnecessary limitations.

I haven't modified the downloadable prompt yet; this is the adjustment I'd recommend based on the examples you uploaded.

now add it to the study stuido prompt and provide the whoel thing as a txt file to download the whole prompt

---

I've updated your **complete Study Studio Prompt 1** with the new **Balanced Explanation Length and Depth** instructions.

📄 Download Your Complete Updated Prompt

What's included?

- ✅ Your entire original Study Studio prompt.
- ✅ The rule against referencing previous lectures or course history.
- ✅ The rule against unnecessary limitations and qualifications.
- ✅ **NEW:** Balanced explanation length—detailed enough to teach each concept thoroughly without becoming excessively long.

- ✅ Natural, professor-style teaching explanations.
- ✅ Complete coverage of important concepts, experiments, mechanisms, and findings.
- ✅ Slide-by-slide organization.

I verified that nothing from the previous prompt was removed or rewritten. Only the new section was inserted.

The goal is to achieve a balance between your earlier Version 6 and the longer Version 7: **comprehensive explanations without unnecessary elaboration or repetition.**

Prompt_1_Study_Studio_Complete_Balanced_Length...
Document

so like give a max words idk length or soemthing

I think adding a word limit would help your Study Studio produce more consistent explanations without becoming excessively long.

My recommendation: 100–150 words per slide

I'd use **150 words as the normal maximum**, with flexibility for complex material.

Slide type	Recommended length
Simple definition or concept	50–80 words
Standard scientific concept	80–120 words
Experiment or research study	100–150 words
Complex mechanism or multiple findings	150–200 words

I wouldn't enforce a strict 150-word ceiling for every slide because some experiments genuinely require more explanation.

Here's the instruction I'd add to your prompt:

SLIDE-BY-SLIDE WORD LIMITS AND EXPLANATION DEPTH (CRITICAL)

Aim for approximately 80–150 words of teaching explanation per slide, adjusting naturally to the complexity of the material.

I'd recommend this over a universal 100-word maximum. It should make Version 7 noticeably more concise while preserving the teaching depth you liked in Version 6.

too little

Then I would increase it to **150–250 words per slide**, with a maximum of **300–350 words for particularly complex slides**.

Since you want Study Studio to feel like a professor teaching rather than a short study guide, I think this is a better balance.

Slide complexity	Recommended word count
Simple concept or definition	100–150 words
Standard scientific concept	150–200 words
Experiment or research study	200–250 words
Complex mechanisms, graphs, or multiple findings	250–350 words

Updated instruction for Study Studio

SLIDE-BY-SLIDE WORD LIMITS AND EXPLANATION DEPTH (CRITICAL)

Aim for approximately 150–250 words of detailed teaching explanation per slide, adjusting naturally to the complexity and amount of scientific information presented.

My recommendation is an average of 200 words per slide. That should preserve the detailed teaching style you want while preventing individual explanations from becoming unnecessarily long.

too little

Then I think **300–500 words per slide** would be a better fit for your Study Studio.

You want detailed, professor-style explanations that genuinely teach the material, but you also don't want the excessive length and repetition you noticed in Version 7.

Recommended word counts

Slide complexity	Word count
Simple concepts or definitions	150–250 words
Standard scientific concepts	250–350 words
Experiments and research findings	300–450 words
Complex mechanisms, experimental results, or detailed graphs	400–600 words

My recommendation: Aim for 350–400 words per slide, with flexibility up to 600 words for complex material.

Updated Study Studio instruction

SLIDE-BY-SLIDE WORD COUNT AND EXPLANATION DEPTH (CRITICAL)

Aim for approximately 300–500 words of detailed teaching explanation per slide, adjusting naturally to the complexity, scientific content, and instructional importance of the material.

Simple slides may require 150–250 words, while standard scientific concepts should generally receive 250–350 words. Slides containing experiments, research findings, or detailed mechanisms may require 300–450 words.

Particularly complex slides containing multiple important concepts, experimental conditions, mechanisms, graphs, or research findings may extend to approximately 500–600 words when necessary.

These ranges are flexible guidelines rather than strict requirements. Never add unnecessary information to reach a word count or remove essential scientific details to remain within one.

Prioritize thorough conceptual explanations, scientific accuracy, and natural professor-style teaching. Explain the material completely while avoiding unnecessary repetition, excessive qualifications, redundant examples, and overly detailed descriptions of visual elements.

The goal is approximately 350–400 words per slide on average, with 500 words as the normal upper target and 600 words reserved for especially complex material.

One important distinction: **I would not force every slide to reach 300 words.** Some slides contain only one straightforward concept, while others contain several experiments. Giving them identical lengths would recreate the excessive elaboration you're trying to avoid.

This range provides substantial teaching depth while letting the actual scientific content determine how much explanation is needed.

SLIDE-BY-SLIDE WORD COUNT AND EXPLANATION DEPTH (CRITICAL)
Aim for approximately 300–500 words of detailed teaching explanation per slide, adjusting naturally to the complexity, scientific content, and instructional importance of the material.
Simple slides may require 150–250 words, while standard scientific concepts should generally receive 250–350 words. Slides containing experiments, research findings, or detailed mechanisms may require 300–450 words.
Particularly complex slides containing multiple important concepts, experimental conditions, mechanisms, graphs, or research findings may extend to approximately 500–600 words when necessary.
These ranges are flexible guidelines rather than strict requirements. Never add unnecessary information to reach a word count or remove essential scientific details to remain within one.
Prioritize thorough conceptual explanations, scientific accuracy, and natural professor-style teaching. Explain the material completely while avoiding unnecessary repetition, excessive qualifications, redundant examples, and overly detailed descriptions of visual elements.
The goal is approximately 350–400 words per slide on average, with 400 words as the normal upper target and 500 words reserved for especially complex material.

okay add it to the study studio and provide the txt file the whole oromt

---

I've added your **Slide-by-Slide Word Count and Explanation Depth** section to the complete Study Studio prompt.

📄 Download Your Updated Study Studio Prompt

The updated prompt includes your requested word-count guidelines:

- **150–250 words:** Simple slides
- **250–350 words:** Standard scientific concepts
- **300–450 words:** Experiments and research findings
- **Up to 500–600 words:** Particularly complex slides
- **350–400 words:** Target average per slide

I preserved **all existing instructions** and inserted your new section without removing or rewriting anything.

One small detail: your final sentence specifies 500 words for especially complex slides, while an earlier sentence permits 600. I've kept your wording exactly as provided, with the ranges treated as flexible guidelines.

Prompt_1_Study_Studio_Complete_With_Word_Count...
Document

i said this The goal is approximately 350–400 words per slide on average, with 400 words as the normal upper target and 500 words reserved for especially complex material.

You're right! You specifically requested **350–400 words per slide on average, with 400 words as the normal upper target and 500 words reserved for especially complex material.**

I've corrected the conflicting word-count instructions so they follow your requested limits.

Download Your Corrected Study Studio Prompt

The complete prompt is included, with all other instructions preserved.

Prompt_1_Study_Studio_Complete_Word_Count_Corr...
Document

make a version that is less than that so make maybe 400 words stop 300 words usual idk

---

I've created a **shorter version of your complete Study Studio prompt**, with approximately **300 words per slide** as the usual target.

Download the Updated Prompt

Updated word-count guidelines

Slide complexity	Word count
Simple concepts	150–200 words

Slide complexity	Word count
Standard scientific concepts	250–300 words
Experiments and research findings	300–350 words
Particularly complex material	Up to 400 words

The goal is approximately 300 words per slide on average, with 350 words as the normal upper target and 400 words reserved for especially complex material.

All other Study Studio instructions remain unchanged.

Prompt_1_Study_Studio_Complete_300_Word_Avera...
Document

or even less

I think **200–250 words per slide** would be a better balance. You'll still get detailed, professor-style explanations, but without the excessive length.

Updated word-count guidelines

Slide complexity	Word count
Simple concepts	100–150 words
Standard scientific concepts	175–250 words
Experiments and research findings	250–300 words
Particularly complex material	Up to 350 words

Target average: Approximately 225 words per slide.
Normal upper target: 300 words.
Maximum for especially complex slides: 350 words.

I've updated the complete Study Studio prompt with these guidelines while preserving the other instructions.

Download the complete updated prompt

This version should give you substantial explanations without making every slide unnecessarily lengthy.

Prompt_1_Study_Studio_Complete_225_Average_350...
Document

Pasted text(2026...
Document

-

- **Setup:** In both conditions, a baby was playing with an object, and a novel word was used to label that same object. The difference was who provided the label and whether the baby could see them.
- In the **joint attention group**, an adult who was interacting with the baby labeled the object the baby was playing with. The baby could see the adult and could tell that the adult was focused on the same object.
- In the **no joint attention group**, a voice from behind a screen labeled the object the baby was playing with. The baby heard the word while holding the object, but could not see the speaker or tell what the speaker was attending to.
- **Observation: 18-month-olds learned the novel word in the joint attention group but not in the no joint attention group.**
- **Interpretation:** In both groups, the word was heard at the same moment the baby was focused on the object. So simply pairing a word with an object in time was not enough. The babies learned the word only when they could see that the speaker was attending to the object as well.
- **Conclusion:** By 18 months, children do not just link any word they hear to whatever they happen to be looking at. They rely on shared attention with the speaker to decide what a new word refers to.

this is great but the thing is i dont want labels liek this again it just has to happen where in the thing did it become a requirments to do it like this

I found exactly where this is coming from in your prompt.

Under **STYLE I WANT (IMPORTANT)**, you have this instruction:

> **Experiment rule:** if the content includes an experiment or test, explain the setup, observation, interpretation, and conclusion using nested sub-bullets.

That's the problem. Claude is interpreting that instruction as a requirement to organize experiments into labeled parts:

- **Setup:**
- **Observation:**
- **Interpretation:**
- **Conclusion:**

But that's not what you want. You want all four elements explained naturally, without explicitly labeling them.

Here's how I would change that instruction

Replace the existing experiment rule with:

EXPERIMENT EXPLANATION RULE (CRITICAL)

When explaining experiments or research studies, naturally incorporate the experimental setup, conditions, procedures, observations, results, interpretations, and conclusions into the teaching explanation.

Do not use artificial labels such as "Setup:", "Participants:", "Procedure:", "Observation:", "Results:", "Interpretation:", "Conclusion:", "Findings:", or "What the task requires:" to organize the explanation.

Instead, explain the experiment through connected, complete sentences that flow naturally, as a knowledgeable professor would when describing a scientific study to students.

Maintain the existing bullet and sub-bullet structure, but allow the scientific content to determine how the explanation is organized. Do not force every experiment into the same sequence of labeled components.

Preserve all important experimental details, comparisons, findings, and scientific interpretations. The goal is to explain the complete study naturally without making the notes resemble a formal laboratory report.

Here's how your example should look instead

Joint Attention and Word Learning (Baldwin et al.)

- Baldwin and colleagues investigated whether **joint attention helps 18-month-old children learn new words**. In both experimental conditions, infants were playing with an object while hearing a novel word used to name that object. The important difference was whether the infant could see the person providing the label.
    - In the **joint attention condition**, an adult interacted directly with the infant and labeled the object the infant was playing with. The infant could see that the adult was attending to the same object.
    - In the **no joint attention condition**, the infant heard the word spoken by someone behind a screen. Although the infant was holding the object when the word was spoken, the speaker's attention was not visible.
- **The 18-month-olds successfully learned the new word in the joint attention condition, but not in the no joint attention condition.** Both groups heard the word while attending to the object, so the difference in learning depended on whether the infants could identify the speaker's attentional focus.
    - This finding suggests that **joint attention plays an important role in early word learning**. Infants use information about what another person is attending to when deciding what a new word refers to.

This keeps the same scientific information and teaching depth while removing the rigid labels.

I would replace the existing experiment rule rather than simply add another instruction. Otherwise, your prompt would contain two conflicting requirements, and Claude might continue using those labels.

great now make th eupdated promot thing an give me the downlaodable full promot as a txt file

---

I've updated your **complete Study Studio prompt** with the new experiment explanation rule.

📄 Download Your Updated Study Studio Prompt

What's changed?

I replaced the original experiment rule so that:

- **No more rigid labels** such as “Setup,” “Observation,” “Interpretation,” or “Conclusion.”
- Experiments are explained naturally through connected, complete sentences.
- The existing **bullet and sub-bullet structure** is preserved.
- All important experimental conditions, findings, and conclusions are still covered.
- The explanations maintain your preferred **professor-style teaching script**.

I also preserved your latest word-count preferences: approximately **200–250 words per slide**, with up to **350 words for especially complex material**.

Everything else in your original Study Studio prompt remains unchanged.

Document

okay connect to my github and find everything all info inthe NEUROETHOLOGY AND BEHAVNEUR-392 repository; honestly just look at all the repository but mainly the BEHAVNEUR-392 one right now

I found your repositories through your connected GitHub account, including the two you mentioned.

Your main repository is BEHAVNEUR-392-. It contains approximately **4,023 files**, organized around 15 numbered chapters, with additional versions and supporting materials.

I also found NEUROETHOLOGY, which contains approximately **4,458 files**, and a third repository, Neuroethology-Course, containing course website materials.

These are substantial projects rather than simple collections of lecture notes. They contain presentation files, scientific figures, research references, videos, source data, scripts, and documentation.

I'm focusing the detailed review on **BEHAVNEUR-392-**, as requested.

Detailed review: BEHAVNEUR-392-

I've now inspected the repository structure and read its main documentation, course specifications, teaching requirements, and chapter-generation instructions.

1. What this repository is

BEHAVNEUR-392- is a project for developing a complete undergraduate **Behavioral Neuroscience 392** course.

Its documented design combines foundational neuroscience with primary research, using substantial lecture presentations rather than brief instructional slides.

The course is organized around *Physiology of Behavior*, 13th edition, by Carlson and Birkett.

The repository specifies:

- **19 planned textbook chapters**, with Chapters 1–15 currently represented.
- Approximately **75–85 slides per lecture**, with authorized exceptions.
- **30–40% foundational neuroscience** and **60–70% primary research**.
- Three substantive teaching paragraphs per content slide.
- Detailed speaker notes written in accessible, professor-style language.
- Original scientific figures, credited images, and embedded research videos.
- Automated checks for slide layout, scientific sources, media, and formatting.

2. Chapters currently represented

Chapter	Subject	Reported slides
1	Foundations of Behavioral Neuroscience	75; expanded revision 90
2	Electrical and Chemical Neural Signaling	75
3	Nervous System Anatomy	75
4	Psychopharmacology and Neurotransmitters	75
5	Research Methods and Neuroengineering	86
6	Vision and Visual Processing	90
7	Somatosensation, Balance, Pain, Taste, and Smell	75
7A	Peripheral Auditory System	80
7B	Central Auditory Processing, Speech, and Music	100
8	Neural Control of Movement	75
9	Sleep and Biological Rhythms	86

Chapter	Subject	Reported slides
10	Reproduction, Hormones, and Parenting	80
11	Emotion	80
12	Hunger, Thirst, and Ingestive Behavior	80
13	Learning and Memory	80
14	Human Communication and Language	80
15	Neural Development and Neurodiversity	80

These counts come from the repository's documentation; they are not an independent slide-by-slide verification of every PowerPoint.

3. The scientific and instructional approach

One particularly important feature is that the repository does **not** treat behavioral neuroscience as merely human brain anatomy.

It integrates cellular neuroscience, neurophysiology, animal behavior, experimental techniques, cognitive neuroscience, and comparative research.

For example, the auditory material is divided into peripheral hearing and central auditory processing. The central lecture also incorporates speech, music, auditory attention, communication, and comparative behavior.

The research-methods chapter includes neuroengineering and newer approaches to measuring and manipulating neural activity.

The repository's teaching guidelines emphasize explaining exactly what a neuron, receptor, molecule, or experimental manipulation does, rather than simply listing technical terms.

4. The relationship to NEUROETHOLOGY

The two repositories are related, but they have different purposes.

NEUROETHOLOGY is organized around individual lectures and contains thousands of scientific figures, research references, media assets, and lecture-generation files.

BEHAVNEUR-392- reuses some of the technical infrastructure developed for NEUROETHOLOGY, while maintaining separate course content and requirements.

Importantly, the BEHAVNEUR-392- instructions explicitly prefer **different primary research papers** from those already used in NEUROETHOLOGY whenever appropriate.

That helps the courses remain scientifically complementary rather than duplicating the same studies.

5. What I found particularly interesting

The repository contains substantial quality-control infrastructure, including:

- Slide-building and validation scripts.
- Scientific image-cropping utilities.
- Video provenance and source records.
- Chapter-specific research bibliographies.
- Checks for the required length of teaching paragraphs.
- Documentation of revisions and media corrections.

For example, Chapter 14 underwent a documented revision on October 22, 2026, replacing 26 recordings that did not adequately match their corresponding scientific concepts.

That suggests the project is being refined for instructional accuracy, not simply expanded by adding more slides.

6. Current review status

I have established the repository inventories and examined the central documentation, but **I have not yet independently read all 4,023 files in BEHAVNEUR-392- or all 4,458 files in NEUROETHOLOGY**. In particular, I haven't verified every scientific claim, paper, image, or embedded video.

I also haven't changed anything in your GitHub repositories.

The main finding so far: BEHAVNEUR-392- is a substantial behavioral neuroscience course-development project with a strong emphasis on primary research, visual scientific evidence, and accessible teaching explanations. Its relationship with NEUROETHOLOGY is especially useful because the two projects can share production tools while developing distinct scientific content.

I can use these repositories as source material for our subsequent discussions, including reviewing individual chapters, evaluating the neuroscience, identifying overlap between courses, and improving lecture content.

great what was the last thing we made for BEHAVNEUR 392

The **last thing we worked on in BEHAVNEUR-392 was Chapter 14**, but the **last new lecture we created was Chapter 15**.

Here's the distinction:

🧠 Last new lecture: Chapter 15

Building the Brain: Development, Experience, and Neurodiversity

Created on **October 20, 2026**, alongside Chapter 14.

The lecture includes:

- **80 slides** (78 teaching slides).
- **40 embedded videos**.
- **31 foundational slides and 47 research slides**.
- **234 teaching paragraphs** with matching speaker notes.
- Topics including neurogenesis, neuronal migration, axon guidance, synapse formation, critical periods, autism, ADHD, and neurodiversity.

View Chapter 15 on GitHub

🔬 Most recent work: Chapter 14 revisions

From Words to Meaning: The Neural Systems of Human Communication

On **October 22, 2026**, we revised Chapter 14 to correct mismatches between embedded videos and the neuroscience being taught.

Specifically, the repository records that **26 videos were replaced** to better match topics such as aphasia, reading, speech production, and neural communication.

The most recent commit, dated October 22, documented the verified download links for that corrected lecture.

View the latest GitHub commit

So we're currently up to Chapter 15 in terms of creating new lectures. Chapter 16 would be next if we're continuing sequentially through the textbook.

no do a deep search because we did more look through all repositiry etc

---

okay so for the BEHAVNEUR 392 find all of the pptx that we made like the last update we made for all that i accepted and mvoed onto next so tell me when you found them

---

oh so it was not 26?

oh okay so for each one of the 23 provide a pdf of it and zip it; each pdf needs to be under 29 mb so all 23 as pdf and zip

---

The full 23-PDF ZIP has not yet been produced here. I wanted to make that distinction clear rather than give you an incomplete archive labeled as complete.

what do you mean do the zip files not have the pdfs?

Pasted text(2026...
Document

extract the zip file and now like okay so

look at all the files and specifically just understand how we did it

the thing i still do not like is the 3 paragraphs so what i want you to do is like keep eveything the same like tell it not to change anything like embeded figures etc only thig we will edit is 3 paragraph text,

first i want to see how it would look like with subbulets and stuff like

how we do for the thing but then a 3 paragraph style one; and more like how we set up the latest prompt 1-3

i like this one

obviously because we want to fix the text only the outputs like 1/2 is not necessary and stuff etc; and also like i think i enforced articles photos only but like general photos also okay like for example if where looking at neuron talking about a membrane you can provide general photos from it from web just cite them; no ai photos tho; like need to be reliable; primary paper emphasis but photos from textbooks; photos for like general ppublic okay and stuff

like for exampke were talking about a monkey provide a general like getty image of that specific monkey etc; like dont use these specific examples but liek generalize it to understand if that makes esnse

no do it here

---

firstn just analyze it

layout_samples.png
Image

provide it as a downladable pdf the png but not connecting or opening by side downloading to comptutee

BEHAVNEUR392_Slide_Layout_Examples.pdf
PDF

so what is this shwoing the png im confused

The PNG I created shows **six examples of how your BEHAVNEUR 392 PowerPoint slides currently look**.

It is **not a redesigned version** of your slides.

I put those six examples together so we could examine your existing formatting before deciding what to change.

What you're looking at

Each example contains:

- **Top:** The original slide title.
- **Left:** The three paragraphs of teaching text that you want to improve.
- **Right:** The existing scientific figures, diagrams, or photographs.
- **Bottom:** The original citations and slide information.

What I was trying to demonstrate

Your slides currently follow the same structure: **three blocks of explanatory text alongside scientific visuals**.

You mentioned that you don't particularly like how those three paragraphs read. You want to see whether structured bullets and sub-bullets would make the explanations clearer while preserving the natural, detailed teaching style.

What I haven't shown you yet

I haven't created the comparison you actually wanted:

Version A — Bullets and sub-bullets

The existing three paragraphs rewritten into detailed teaching bullets, with sub-bullets explaining mechanisms, experiments, and findings.

Version B — Improved three-paragraph format

The same scientific information rewritten into three natural, connected paragraphs using the principles from your latest teaching-notes prompt.

Both versions would preserve the original figures, citations, embedded media, and overall design.

So the PNG is simply a reference showing your current slides, not an example of the proposed changes.

okay provide version a and version b example; again avoid like how we did it orignal

as a png like how im asking above

BEHAVNEUR392_Versions_A_vs_B_Comparison.png
Image

allow me to download it without requiring connection

BEHAVNEUR392_Version_A_Subbullets.png
Image

BEHAVNEUR392_Version_B_Three_Paragraphs.png
Image

BEHAVNEUR392_Versions_A_vs_B_Comparison.png
Image

i really like it but i want it to align with my prompts 1-3 like latest updates; not the study studio i understand it can reach max 300 but still follow the 3 paragraphs with bullets etc; i like that and stuff the only thing is that for everything i want it to be teaching material im done with teaching like limitations because i simply dont care i dont want to say

Actin does more than act as a fixed support structure. Its organization changes as a neuron develops. The researchers proposed that traveling actin waves alter local growth and transport, helping immature processes explore their surroundings. Such changes contribute to the development of the cell's future receiving and sending compartments.

ehh like for both the sub bullets and the other like i want it to teach like like how we have done with the prompts and set the requirment if that makes sense so like make another example to see

---

like youre making prompt 4 for this thing that im asking to do

revision prompt 4 revision of text or something idk

BEHAVNEUR392_Prompt_4_Teaching_Text_Revision....
Document

BEHAVNEUR392_Prompt_4_Teaching_Text_Revision....
Document

BEHAVNEUR392_Prompt4_Version_A_Teaching_Bulle...
Image

2 more

okay so version 4 i want you to say to keep everything the same use the prompt like exactly same structure like how ive said but say this is for edditing to powerpoints in Behavneur 392 the 23 lectures with emedded video it has to be the last one made and approved not earlier versions; but yea pretty much keep like the wriitng of how ive but it; also improtant lot more bold things i dont like when lots of stuff are unbolded but obviosouly for critical dont just bold to bold;

but make sure to say that they will be doing version a and version b but nothig like videos the text etc; cannot cahnge the title for slide can change that is acceptable but not recommended; keep eveyrthingpretty much the same only keep text;

do not include the photo thing i talked about we will include that in a later prompt dont meniton this tho

make the prompt; again follow like all the files i provided like the prompt to make these powerpoints and stuff dont use that but like reference it because i want the text it in one textbox not sepeate textboxes if that makes sense textbox with its bullet and subbulet not like text bok bulet textbok subbpllet just put it together but follow spacing and stuff;

but first before anything so like on average how many lines can we fit with 3 paragrpah in version b

and bullet subbulet with version a

like i want to know so its not obvisouly os much but not obicously so little theres a lot of white space; but also dont want to take over the whole slide so like is what we have now good what do you think

also im sure its mentioned but like slides never refer to past etcl like i never do that if that makes sense

---

BEHAVNEUR392_Prompt_4_Final_Teaching_Text_Re...
Document

wait i didnt say to creat the prompt 4 yet maybe i did but before that

1. How much text should fit on each slide?

I checked the actual PDFs from Chapters 2, 4, and 13, rather than estimating from the screenshots. Across 132 instructional slides, the existing left-side teaching text averages approximately 17–18 rendered lines per slide.
My recommendation is to keep roughly that amount of text. Your current slides have a good balance between teaching explanations and scientific figures. The problem is more about how the sentences teach than how much space the text occupies.

Version A

15–18 lines

Bullets and sub-bullets
Three substantial teaching groups with nested explanations.
Indentation uses some horizontal space, so fewer words may fit.
Version B

16–19 lines

Three teaching paragraphs
Approximately 5–6 wrapped lines per paragraph, with comfortable spacing between them.
These are recommended visual targets, not rigid limits. A complicated mechanism may need another line; a simpler concept should not be padded with filler

how me this how it would loko like first before we actually do the prompt like the prompt is great keep it exact but let me apprve first because we might need to reduce

BEHAVNEUR392_Line_Count_Comparison_17_vs_18.p...
Image

BEHAVNEUR392_17_Line_Version_A_Preview.png
Image

BEHAVNEUR392_18_Line_Version_B_Preview.png
Image

allow me to download without opening the side bar or requiring connection like i click on it and the download button just automtically appears on my edge thing

---

I've packaged all three PNG images into **one ZIP file** so Edge should download it instead of opening the images in the sidebar.

📥 🗄 DOWNLOAD ALL 3 PNG IMAGES — ZIP

Included:

- Version A — 17 lines
- Version B — 18 lines
- Side-by-side comparison

No GitHub connection or external website is required.

Note: I can't control whether Edge opens a preview or downloads automatically. ZIP files generally trigger a download. If it doesn't, right-click the link and select **Save link as**.

Prompt 4 remains unchanged until you approve the examples.

great i like the version here so like do i use the prompt u gave above the full one

Yes! You can use the full Prompt 4 I gave you above. Since you approved the latest spacing examples, the prompt is ready to use.

📥 Download Prompt 4

What it will do

The prompt instructs the AI to:

1. **Use only the latest approved versions** of all 23 BEHAVNEUR 392 PowerPoints, including their embedded videos.
2. **Create both versions:** Version A with teaching bullets and sub-bullets, and Version B with three natural teaching paragraphs.
3. **Preserve everything else**, including scientific figures, citations, videos, slide order, and overall design.
4. **Use one editable text box per slide**, containing all three teaching groups.
5. **Follow your latest Prompts 1–3** for scientific depth, natural teaching language, and meaningful bolding.
6. **Maintain the spacing you approved:** approximately 17 lines for Version A and 18 lines for Version B.
7. **Avoid references to earlier or later slides**, presentation narration, vague conclusions, and unnecessary filler.

One important clarification

The full prompt currently says **15–18 lines for Version A** and **16–19 lines for Version B**. That already accommodates the exact examples you approved (17 and 18 lines), so **you don't need to change anything**.

My recommendation: Use the full prompt as written. Just make sure the AI has access to the original editable PowerPoints—not only the PDFs—so it can preserve the embedded videos and other PowerPoint elements.

BEHAVNEUR392_Prompt_4_Final_Teaching_Text_Re...
Document

BEHAVNEUR392...
Document

this one correct?

Yes! This is the correct and complete Prompt 4. ✅

I reviewed your uploaded file, **BEHAVNEUR392_Prompt_4_Final_Teaching_Text_Revision(1).md**, and confirmed that it includes everything we agreed on.

Specifically, it requires:

1. **The latest approved PowerPoints only** — all 23 lectures, with their original embedded videos preserved.
2. **Version A:** Three main teaching bullets with detailed, natural sub-bullets.
3. **Version B:** Three connected teaching paragraphs that directly explain the neuroscience.
4. **One editable text box per slide** — including all bullets and sub-bullets, rather than separate text boxes.
5. **Your approved spacing:**
    - Version A: Approximately 15–18 lines.
    - Version B: Approximately 16–19 lines.
6. **More meaningful bolding** of important scientific terminology, mechanisms, structures, and findings.
7. **No references to previous or upcoming slides**, course history, or presentation structure.
8. **Everything else stays unchanged** — figures, videos, citations, slide order, design, and other content.
9. **46 finished PowerPoints:** 23 Version A and 23 Version B, without overwriting the originals.

It also correctly specifies that the AI must **create a representative A/B comparison before processing all 23 lectures**.

You don't need to change anything. This is the finalized Prompt 4 you approved.

okay what size did you use for version a and version b

Worked for 12s

I've packaged all three PNG images into **one ZIP file** so Edge should download it instead of opening the images in the sidebar.

📥 DOWNLOAD ALL 3 PNG IMAGES — ZIP

Included:

- Version A — 17 lines
- Version B — 18 lines
- Side-by-side comparison

No GitHub connection or external website is required.
Note: I can't control whether Edge opens a preview or downloads automatically. ZIP files generally trigger a download. If it doesn't, right-click the link and select **Save link as**.
Prompt 4 remains unchanged until you approve the examples.

because if we make version b size smaller we can fit more text idk or am i wrong ; you always have the freedom to tell me im wrong

lets see try a smaller text for both to see

---

lets see try a smaller text for both to see

so that means is fill in space or add more lines like version a could also get a bit more light maybe 1 or 2 idk

like im talking about version A like it could have more bullets idk

okay like show me how more to a would look

Yes — this is the kind of change I think you mean for **Version A**: **more bullet structure**, not just more text.

I made a new mockup where Version A has:

- **4 main bullets** instead of 3
- **7 sub-bullets total**
- the same slide, same figures, same citations, same title
- just a more segmented teaching structure

Direct download

Download ZIP — Version A with more bullets

That ZIP includes:

- the new **Version A with more bullets**
- a **comparison image** against the earlier Version A

Quick summary of this test version

- **Main bullets:** 4
- **Sub-bullets:** 7
- **Style:** still full teaching sentences, not fragments
- **Goal:** make the explanation easier to scan and teach aloud

My opinion

Yes, this works better for Version A if you want it to feel more structured.

I think the best rule for Version A may be something like:

- **3–4 main bullets**
- **1–3 sub-bullets under each main bullet**
- flexible based on the science on that slide

That would be better than forcing exactly 3 bullets every time.

If you want, next I can do one of these:

1. **an even more bullet-heavy Version A**
2. **a cleaner Version A with 4 bullets but slightly shorter sub-bullets**
3. **tell you the exact Prompt 4 change** so Version A allows more bullets like this without affecting Version B

Yes! You can use the full Prompt 4 I gave you above. Since you approved the latest spacing examples, the prompt is ready to use.

📥 Download Prompt 4

What it will do

The prompt instructs the AI to:

1. **Use only the latest approved versions** of all 23 BEHAVNEUR 392 PowerPoints, including their embedded videos.

Prompt 4 remains unchanged until you approve the examples.

because if we make version b size smaller we can fit more text idk or am i wrong ; you always have the freedom to tell me im wrong

I checked the original code used to create the PNG previews, so I can give you the exact font sizes, not estimates.

	Version A — Bullets	Version B — Paragraphs
Main text	28 px	29 px
Sub-bullets	27 px	N/A
Line spacing	39 px	37 px

Total wrapped lines	17	18
Approximate PowerPoint equivalent*	21 pt	21.75 pt

*These are image-rendering sizes, not measurements from the original editable PowerPoints. Point-size equivalents assume 96 pixels per inch.Would making Version B's font smaller help?
Yes, you're correct. A slightly smaller font could allow more scientific explanation without increasing the size of the text area.

However, I wouldn't reduce it dramatically. Your slides already have a good balance between text and figures, and you want to be able to read the explanations comfortably while teaching.

Here's what I would consider:

Version B font	My assessment
29 px — current	Very readable, but fits less text
28 px	Best option to test next
27 px	May fit noticeably more, but risks looking dense
25–26 px	I wouldn't recommend this as the default

There's another consideration: reducing the font size doesn't automatically mean we should add more content. Your biggest priority is replacing vague statements with specific mechanisms, experimental observations, and explanations. A smaller font is useful only when that additional information improves the teaching.

My recommendation: Keep Version A at 28 px for its main bullets and 27 px for sub-bullets. Test Version B at 28 px instead of 29 px, keeping the same paragraph spacing and original slide layout.

That is a small reduction—about 3.4%—so it might allow an additional wrapped line or two, depending on the text. I would review the result visually before changing Prompt 4.

And you're right to question the font sizes rather than accepting the previews as final. We should optimize for readability and depth together, not simply fill every available space.

lets see try a smaller text for both to see

Worked for 38s

I've made smaller-font previews for both versions, using the same teaching text and original scientific figures. Nothing else has changed.

New comparison — smaller text

	Previous example	New smaller example
Version A — Main bullets	25 px	23 px
Version A — Sub-bullets	24 px	22 px
Version B — Paragraphs	27 px	25 px

The new versions have more breathing room below the text. That extra space could accommodate a few additional lines of scientific explanation, although the current text itself hasn't been expanded.
Download all three PNGs
Download smaller-font previews — ZIP

This includes Version A, Version B, and the side-by-side comparison. The ZIP should download directly in Edge.

My preference: The smaller Version B looks promising because it creates more room without substantially reducing readability. Version A might benefit more from keeping its previous font size, since indentation already makes sub-bullets narrower.

Prompt 4 remains unchanged. We can decide which font sizes you prefer before updating its requirements.

like ignore what you did in that section thats when it went back you want to refer to the thing

this one
BEHAVNEUR392_Prompt_4_Final_Teaching_Text_Revision.txtDocument

but all im asking is for the font to be smaller but more text to be added obviously teaching because their is still white space; where i put the 2; so analyze all file the one i attatched but also files i have uploaded to the conversation specifically the ones i am asking

BEHAVNEUR392_Original_Arial_Smaller_Font_More_T...

Document

why is there 2

okay now using this whole conversation from the top **use GitHub to save this whole onversation in jordanxxlopez/BEHAVNEUR-392-?**

in my github for 392 give it like title 10/31 so its easy to find so name this one lemon and stuff

okay so like for example go through my github and find cherry but now for this chat name it lemon

this below was from the other chat

okay save this whole chat to the github repository store it in memory like the beginning chats etc just store it
8:38 PM
Worked for 1m 35s
Saved to your GitHub repository:

- **Complete available chat history, including the earlier pasted chats**
- **Continuation memory: preferences, decisions, and completed work**

Added a reference in `AGENTS.md` so future repository work can find it.
8:39 PM
User attachment
like the whole thing like files the chats etc; like idk which one i guess give it all
8:40 PM
Worked for 2m 9s
Saved everything together in **your GitHub session archive**:

- Chat history, including the earlier pasted chats
- All 23 PDFs and links to the 23 latest PowerPoints
- Complete creation rules and history
- Screenshots, scripts, and verification records
- Continuation memory

The actual files are preserved; large duplicate ZIP wrappers aren't included. You don't need to choose anything from that menu.
8:42 PM
give it a name like 10/31 so its easy to find name this on cherry
8:42 PM
Worked for 12s
Renamed this chat **10/31 — BEHAVNEUR 392 Archive**.
8:42 PM
no name it cherry because were name multile 10/31
8:42 PM
Worked for 4s
Renamed this chat **Cherry**.
8:42 PM
no for the thing saved like the whole thing saved to the github like git it a name with the date but then name it cherry

8:43 PM
Worked for 29s
Renamed the saved GitHub archive **2026-10-31_Cherry**.
Open Cherry — 10/31
8:43 PM

so like find it and do it like how we did for cherry etc like saving lal the

also make sure to copy like deeep line as makdown working directory evyething

name this oen lemon; cherry has already been made but find it

---

no do not reuse files im not sure what you are saying but what you need to do is upload this full chat "rewrite for readability" to github

not the text but eveyrthing from files to the directory idk what every was in this chat from the thinking everything

well how can we get the full thing from this chat not a summary etc

okay do all what you just said

https://chatgpt.com/share/6ae6b8db-41a0-83e8-9896-b64dcabbee1b

---

okay so full thing for lemon is in git hub correct?

okay dohttps://chatgpt.com/share/6ae6bad6-d408-83e8-bbe5-535dd9a2966b

okay analyze the link first wati for it to load and analyze it you can you my computeer
